A woman, aged 24 years, had suffered from bunion since she was 10 years of age. The feet exhibited in a severe degree the condition characteristic of this deformity. The great toe was thrust outward so that there was a partial dislocation at the metatarso-phalangeal joint, and the head of the metatarsal bone was unduly prominent. It is interesting to notice (as I have shown in other cases) that where joint surfaces are not in contact the loss of functional activity leads to wasting of the articular cartilage. Thus it was seen, when this case came to be operated upon, that the articular cartilage over the inner third of the head of the metatarsal bone was much atrophied, and at the edge had almost disappeared. In older people there is often an irregular outgrowth of bone in this situation giving an additional prominence to its inner border. Over the prominence there was the characteristic circle of thickened and hardened skin between which and the bone there was a well developed bursa. The tendon of the extensor of the toe stood out tensely beneath the skin. This deformity is no doubt produced by wearing boots of which the inner edge slopes towards the middle line of the sole—a foolish fashion provocative of other evils besides bunion; some of the worst cases, however, occur in persons the subjects of osteo-arthritis, a disease which greatly aggravates the deformity. For such a condition as this patient exhibited the most satisfactory treatment is excision of the metatarso-phalangeal joint and of the bursa over it and the division of the tendon of the extensor of the toe. This having been done the toe was easily brought into a line with the inner border of the foot and fibrous ankylosis has taken place in that position. We took care that the patient had a pair of properly-shaped boots and in these she can walk quite comfortably. This operation seems to me to be much more likely to give satisfactory results than excision of a wedge of the metatarsal bone; in some cases, however, it is sufficient to remove the metatarsal head and to leave the base of the phalanx.

In slight and early cases division of the extensor tendon and forcible straightening of the toe may be practised, but this must be followed by the use of a digitated stocking and a wedge of felt between the first and second toes; or a boot may be worn with a separate division for the first toe. A spring splint should also be worn at night. But excepting for these slight cases the splints, springs, and other kinds of apparatus which have been invented for the treatment of bunion are worse than useless.

One other case which I will briefly allude to is that of a boy, aged 15 years, who was admitted to hospital on account of lameness due to the condition known as "hallux rigidus." The patient is employed in the post office and has much standing. There was a slight degree of flat-foot, and the right metatarso-phalangeal joint was rigid, painful, and incapable of voluntary movement. The position of the bones was not altered and there was no pain on moderate inter-articular pressure, but any attempt to walk or to bear any weight on the foot gave severe pain. I treated this boy for some time as an out-patient (as he was anxious not to give up work), supporting the arch of the foot, taking off pressure from the painful joint, &c., but with no benefit. He was therefore taken into the hospital and I excised the head of the metatarsal bone. This relieved him of pain and enabled him to walk with comfort. I could discover no disease of the bone or articular cartilage; the only abnormality seemed to be that the joint surfaces were fixed rigidly in close contact but without any real ankylosis.

Presidential Address

ON

THE PRESENT POSITION OF PHARMACY.

Delivered at the British Pharmaceutical Conference on July 24th, 1900,

BY E. M. HOLMES, F.L.S.,

PRESIDENT OF THE PHARMACEUTICAL SOCIETY.

LADIES AND GENTLEMEN,—At the commencement of the century chemists and druggists had just begun to separate into a distinct body from grocers and general dealers. But it was not until 1842, when they obtained a Royal charter of incorporation, that they began to assume the character of an educated body. As the semi-professional character of the business became recognised, in consequence of the examination and education that chemists were compelled to undergo, the number of young men entering it gradually increased. These were and are still drawn largely from respectable families with small incomes who, misled by the small amount of capital necessary to start a business and the reputed large profits, do not recognise that the returns are usually so small that the grocer and draper can make eight or ten times more money, even on small profits, than a chemist is able to do. Nor is it generally recognised that the business depends far more than in any other trade on the personal integrity of the proprietor and that it takes time to acquire the confidence of the public. The fact that the keen financial instincts of the Jews have never led them to embark in pharmacy might have served to indicate to the general public that the business of the chemist and druggist is not so lucrative as is generally supposed. The wills of pharmacists never present large figures and millionaires are unknown in British pharmacy. Nevertheless, the supply of dispensers of medicine has exceeded the public demand. The principle of free trade has prevented such a limitation of the number of those engaged in pharmacy as is prevalent in some other countries, with the result that, like all other trades and professions in this country, its ranks are overcrowded. At the present time there are about 15,600 registered chemists and druggists, of whom it is estimated that about one-tenth only, whom for convenience we will call pharmacists, actually derive their principal income from the dispensing of prescriptions, a small number from what is known as counter-prescribing, and the remainder from light retail and dispensing business, the dispensing being a comparatively small proportion. In some parts of the country, especially in Scotland, there is a much larger proportion of pharmacists who dispense medicine than in England. Even in different parts of England, in some towns the medical men almost invariably dispense their own medicines, whilst in other towns a few miles distant the dispensing is done almost entirely by pharmacists for the medical men. The cause of these local differences seems worthy of investigation, which might lead to more uniformity of practice. There is little doubt, as was pointed out last autumn by Dr. D. J. Leech (whose premature decease we all deplore), that the practice of pharmacy by medical men is not only an evil to the pharmacist but a disadvantage to the medical men themselves, and that medical men would gain if, wherever possible, they gave up dispensing. It is obviously for the safety of the public that every dispenser of medicine, whether employed by a pharmacist, by coöperative stores, or by a medical practitioner, should have passed a qualifying examination in the art of dispensing medicines, and that every medical man who dispenses his own medicine should have passed the same examination in the subject as the pharmacist whose duties he takes upon himself. But under the modern system the medical student, although he has the opportunity of taking up a course of pharmacy at a hospital or medical school, is often not very conversant with the

subject. The safety of the public is best secured when the dispensing of prescriptions is checked by a second or third qualified dispenser, as is the case in dispensing establishments where several assistants are kept. In respect of poisons especially the public needs protection, inasmuch as it does not know their properties or their antidotes, and the chemist and druggist—as being familiar with both and therefore capable of devising suitable precautions to safeguard their use and to give advice in cases of accidental or other wrongful uses of them—is obviously the fittest person to sell them, whilst it is probably largely due to his lack of energy and want of business enterprise that the poisonous articles used in the arts and for sanitary, insecticidal, or horticultural purposes have not always passed through his hands.

There is another direction in which the safety of the public is likely to be affected. Drugs vary exceedingly in quality. In order to sell cheaply at a working profit it is necessary to buy cheaply. As prices are lowered by coöperative stores the tendency will therefore be to buy inferior qualities to meet the demand for low prices. In the case of drugs used in medicine this may lead to serious results, since when medicine is required to act quickly and effectively, as in croup or in parturition, &c., if the ipecacuanha or ergot be of inferior quality serious danger to life may result through its want of activity. In Russia, Germany, Scandinavia, and Greece this difficulty is met by a legalised tariff for dispensed medicines. In this country it is left to the public themselves to judge by the British Pharmacopœia which upholds a high standard of purity in medicine, and the importance of asking for "B.P." preparations might well be taught to the laity by the wider use of these two letters on ordinary labels.

It has been stated by medical men that what is known as counter-prescribing by pharmacists is one of the causes why dispensing is not entirely handed over to the latter by the medical profession. The subject is no doubt surrounded with practical difficulties, but probably these are not insuperable. There is no law to prevent a man, however ignorant he may be, from prescribing remedies for himself, his friends, or his household, and it has been stated on high medical authority that it would not be objectionable for persons to apply at a pharmacy "for simple remedies for toothache, muscular pain, or trifling dyspeptic ailments, provided the person seeking relief knew what he was about and was not deceived by the assumption of an authority, or of titles, on the part of the chemist, and provided that such relief was merely to be regarded as first aid, or a temporary expedient" for a definite complaint stated by the patient. But this is a very different state of things from what is known as a prescribing business, in which the chemist goes beyond his province in diagnosing disease and supplying remedies for it. In such business the straightforward plan would be for the proprietor to qualify as a medical practitioner or to arrange with a properly qualified man to see his clients. The converse of this is the medical practitioner who keeps open shop like a chemist, and to whom is largely due the difficulty that the uneducated public find in distinguishing between a chemist's and a doctor's shop. It might be possible, perhaps, for representatives of the medical profession and the Pharmaceutical Society to arrange a conference to make mutual provisions for counter-prescribing by chemists to cease on the one hand and the keeping open shop by doctors on the other. This would need disciplinary powers for both bodies to deal with offenders, but the two bodies united could probably, by a good organisation, bring sufficient influence to bear upon the Government to pass an Act authorising such powers.

The real difficulty for the conscientious pharmacist lies in the impossibility of ascertaining whether the case, very often that of an absent person, comes within the limits of first aid or temporary expedients. This difficulty would probably be met most satisfactorily if a small official work were issued by the General Medical Council or by Government authority to the general public indicating on general lines the premonitory symptoms of dangerous or zymotic diseases such as would distinguish, for instance, an ordinary cold from incipient pneumonia or a sore throat from approaching diphtheria or scarlet fever. Such a work in the possession of the heads of families and on the desk of every chemist might serve to indicate both to the public and the pharmacist a dividing line between first aid and the necessity of medical treatment and supervision.

Another difficulty lies in the fact that in small villages where there is no chemist and no carrier it is difficult for the medical man to avoid dispensing. Here, however, is the opportunity of the enterprising chemist in the nearest town to see that the medical man has a portable outfit which he can carry with him on his rounds. The advantage of such portable medicine chests in country villages and for travellers has already been recognised by enterprising London firms which have adopted and enlarged upon the hint given by Brockedon's compressed potassium bicarbonate of 50 years ago. The increase in the rapidity of travelling and the absence of an international Pharmacopœia has caused a demand for portable medicines which has been increased by the opening up of new countries where it is impossible to obtain medicine, so that a new industry in this direction has been developed in which English pharmacists, with characteristic conservatism, have allowed Americans to take the lead. The great advantage in the saving of time by the use of portable medicines to both the medical practitioner and the patient in country districts where there is no chemist within several miles and where the considerable delay in the delivery of medicine, by reason of the distance, is often of serious importance, is almost certain to lead to the permanent adoption of such time- and labour-saving devices. The value to the public of portable medicine for travelling purposes cannot be denied, as well as to the Government, since in military and naval operations the sudden demands made upon medical stores and appliances necessitate the use of drugs and preparations occupying as little space as possible, in a form as concentrated as is compatible with safety and not readily affected by the vicissitudes of climate. This form of medicine has therefore become a feature of the pharmacy of to-day and is likely to develop still further. It has, however, the disadvantage of placing in the hands of the laity powerful remedies which they are apt to use without proper medical advice and without the ability to judge of the nature of the disease for which they employ them.

The vast number of new vegetable, chemical, and animal remedies introduced during recent years, and the impossibility of keeping pace with them, on the part of the medical men and the pharmacist, especially in the provinces, where as a rule new remedies do not come into use until two or three years after introduction into city practice, has led to the comparative disuse of the Pharmacopœia for prescribing purposes and to more dependence being placed by physicians concerning new remedies upon such works as Martindale's "Extra Pharmacopœia" and Squire's "Companion to the British Pharmacopœia," works which enterprising pharmacists have produced to meet the necessities of medicine and pharmacy during the time that elapses between the publication of one Pharmacopœia and another. These works have also the additional advantage that they contain tables of diseases and of all the most modern remedies used for them, as well as the doses and formulæ showing useful combinations of the various preparations. In these rapidly progressive times the pharmacopœias cannot, even if published decennially, be actually up to date; it can only crystallise into a definite shape formulæ that have already been in use for some time. The Pharmacopœia is now really more used by pharmacists as a standard for insuring uniformity in official preparations than by physicians for prescribing purposes. It is only just, therefore, that pharmacists as a body should have an influential voice in its construction, especially as they have shown by publication of numerous formulæ that have been accepted in the previous pharmacopœias that they are quite capable of devising approved formulæ. The medical profession must, of course, necessarily determine what remedies and preparations shall be included in it for their convenience.

THE PHARMACOPŒIA AS A LEGAL STANDARD.

Many vexatious prosecutions of chemists have resulted from the fact that the British Pharmacopœia has been erroneously supposed by many analysts to be a legal standard for the purity of drugs. The statement in the Pharmacopœia that the work is "intended to afford to the members of the medical profession, and those engaged in the preparation of medicines throughout the British Empire, one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined," in no way indicates that it is to be used as the legal standard of purity for drugs used in commerce for domestic and technical purposes. To prosecute chemists because, for instance, tincture of myrrh, which is

used as a dentifrice rather than as a medicine, or benzoin, which is used in French polish, or soft soap, or ammonium carbonate, soda water, or other articles in regular household use, do not answer to the tests of purity of the B.P. would constitute an interference with trade that would be as absurd as it would be vexatious. That the standard of purity used in dispensing physicians' prescriptions should be as high as it is possible to make it is an article of faith of the British Pharmaceutical Conference, but there are many cases in which drugs and preparations which are B.P. articles are used for other than medical purposes, and for such the average of normal condition of purity meets all the requirements of the case. There is, therefore, a need for a published standard of normal or average purity of drugs for this purpose until such time as the Government realises its duty to publish a legal standard, by which the provisions of the Sale of Food and Drugs Act can be effectively and justly carried out. In the absence of any definite Government standard for drugs this is the work which analysts, in conjunction with pharmacists, should take up, and one that the conference should support in the interests both of the public and of chemists themselves.

There appear to have been several causes that led to the erroneous supposition that the B.P. is a legal standard for the purity of drugs. One is the misleading use of synonyms in the B.P. The names of commercial products in several cases in which they differ considerably in composition from the official article are given as synonyms, such as "milk of sulphur" for sulphur præcipitatum and "soft soap" for sapo mollis. Such synonyms are misleading and serve no useful purpose, since medical practitioners never use them in their prescriptions, and they might well be omitted. Another cause that leads to unjust prosecution is due apparently to the ignorance that exists amongst analysts who are not also pharmaceutical chemists concerning the rapid changes that many vegetable and other preparations undergo when kept in stock. Indeed, it would be a considerable advantage to both analysts and the public if the former were required to pass the major examination of the Pharmaceutical Society before going in for the more stringent chemical examination of the F.I.C., since a knowledge of the physical and histological character of crude drugs is practically essential to the accurate determination of their purity or otherwise.

It may here be remarked that a fear lest the B.P. might be used as a legal standard seems to have had a deteriorating influence on its construction, having apparently led in some cases, such as those of myrrh and aloes, to a lowering of the limits of purity, so that it is possible for very inferior qualities of the same drug to be sold and still meet the B.P. requirements. Such latitude is deplorable, since it leads to unfair competition and affords no security to the public that they get the article they want when they desire that their medicines—for instance, compound liquorice powder, Gregory's powder, or confection of senna—should be of the best quality and effective action, even if prepared according to the B.P.

AN INTERNATIONAL PHARMACOPŒIA.

A general pharmacopœia that would enable a pharmacist to dispense a prescription with uniformity in any pharmacy on the continent may be regarded as a utopian rather than a practical idea and could only be attained by alphabetically arranging in dictionary form all the formulæ in all the known pharmacopœias. But there can be no reason why an approach towards it should not be made by a congress of medical men and pharmacists, limiting their attention, in the first place, to poisonous preparations only, and in order to avoid international jealousies adopting as a standard the formulæ that approach nearest to decimal proportions. The comparison of different formulæ is rendered a simple matter by the publication of the different strengths of preparations of the various pharmacopœias in Squire's "Companion to the British Pharmacopœia." The next step might be to make uniform the strength of the most generally used preparations that are not poisonous. A really useful International Pharmacopœia cannot be otherwise than a gradual growth.

The introduction of standardisation of the more powerful preparations of the Pharmacopœia and the stringent chemical and microscopical tests now ordered in that work to ascertain the purity of drugs cannot be carried out in any but large businesses where several assistants are kept and where one man can devote his whole time to testing drugs and standardising preparations. Hence the personal guarantee of the purity of the preparation he supplies is passing out of the hands of the single-handed retail pharmacist.

The increase of knowledge in every branch of medical science has caused the study of pharmacy and pharmacognosy and dispensing to be somewhat neglected and forced them to occupy a comparatively unimportant position in the curriculum of medical study, so that the act of prescribing is in danger of being lost. The medical practitioner—anxious to utilise the most recent improvements in scientific remedies, but with his time fully occupied in visiting patients and diagnosing diseases—consequently indicates what he requires to the pharmacist who readily supplies him with a list of formulæ compiled from the most recent publications or specially devised to meet the wants of the prescriber who accordingly chooses from those put before him the one he considers most suitable. Naturally, these preparations can be more economically prepared on the wholesale scale. The retail pharmacist has little chance of success unless he can conduct his operations on the large scale and many of the more enterprising are therefore turning their businesses into limited liability concerns. Co-operation is a growth of the times, an outcome of competition. Judging from past history it is as unwise and useless to attempt to oppose coöperation as it was for the courtiers of Canute to ask him to forbid the advance of the sea. Coöperation has come to stay and, like a forest fire, can only be met by similar tactics—i.e., by coöperation. The only hope for a livelihood for those who have not much capital is in coöperating with those who possess it—a coöperation of knowledge with business capacity.

With respect to the use of the titles "pharmaceutical chemist" and "chemist and druggist" by companies it is difficult to find any sound objection to this provided all the members of the company are legally qualified to use it; but where they are not, and company laws are utilised to cover incompetent persons who have possibly failed to satisfy the legally-appointed examiners of their competency to dispense medicine, such an illogical and unjust use of the titles should be uncompromisingly opposed by a thoroughly well-organised political resistance to any Bill proposing it. In other words, no company should be allowed to use a legal title for which its members have not the qualification prescribed by law. The logical result of such a concession would be to nullify the Pharmacy Act, since if one man who fails to pass an examination in pharmacy can join with six others to form a limited liability company which can use the titles of "pharmaceutical chemists" or "chemists and druggists," a number of persons would be able to do what the law has expressly stated one man may not do. The injustice that would thus be done to those who have already expended much time and money to obtain the title is so obvious that it can hardly be possible that disinterested and conscientious legislators could support such a provision for disregarding vested interests or could adopt the principle it would involve of making one law to enable persons to evade another.

Another change noticeable during the latter part of the century has been the enormous increase in the public demand for what are known as patent medicines. This may be seen from the amount derived from the sale of medicine stamps, which has increased from £43,692 in 1860 to £266,404 in 1899. The preparations commonly alluded to under this heading consist in reality of at least three different classes. 1. The quack medicine, a preparation advertised to cure everything, or nearly so. 2. Proprietary medicines, such as chlorodyne, liquor opii sedativus, liquor bismuthi, fluid magnesia, pepsin wine, &c., which have some real value as medicinal agents, and have been so much prescribed by medical men that in many cases official imitations have been introduced into the Pharmacopœia. 3. Proprietary articles for domestic use, such as perfumes, hair lotions, peptonised and pancreatised and malted foods, inhalers, court plaster, and skin soap. The articles in the first class are objectionable from every point o view. But proprietary medicines are often the result of the application of chemical knowledge and pharmaceutical skill in advance of the time, and, as such, and as comprising also the personal element, have a value of their own. So long as they are prepared by one person directly interested in the excellence and uniformity of the production they are even more likely to be uniform in character than a B.P. preparation prepared by different operators within the too often wide limits of quality of drugs allowed by the descriptions and tests of that work. Proprietary

articles, as distinct from proprietary medicines, are usually started to meet a public want, and although their sale doubtless depends largely on advertisement, they would soon go out of use, like date coffee, if they had no intrinsic merit of their own. Those articles, therefore, form a part of the chemist's business that is worthy of attention from another point of view than that of retail sale. Whilst the limit of profit is reduced by the competition of stores to a level at which it does not pay the chemist to keep his money lying idle in stock, the obvious remedy is for the chemist not to retail any proprietary articles except his own or those which are protected by the P.A.T.A.[1] Each chemist should manufacture his own specialty, since the manufacturer's profit is certain and can be arranged at a paying rate, whilst that of the distributor is not so in many cases. The stores and large capitalists by buying in very large quantities can alone make these retail sales pay at the present ruinous prices, and the heavier their stock and the more numerous the articles they are compelled by the demands of the public and by advertisements to keep in stock the less profit they will get, until a time arrives when the interest lost on money lying idle in such stock must lead to the raising of prices or to giving up the sales.

The present state of pharmacy is a somewhat anomalous one. As hitherto practised in this country it consists, like the fabulous mermaid, of two incongruous halves. On one side it is a business which to be successful must be carried out on business lines; on the other side it is a profession which should be conducted in accordance with professional principles. But as both are usually carried on in one room the public finds a difficulty in discriminating between them and concludes that the price paid for the dispensing of medicine represents an enormous profit on drugs, instead of being partly a legitimate profit and partly a very small professional fee, no allowance being made for the skill and knowledge bestowed on the preparation of medicine or for the responsibility of insuring accurate dispensing. This is not to be wondered at if the pharmacist himself does not draw the distinction, but carries on both the business and the profession in one and the same room. Patent medicines and packed goods and ready-made preparations which require no skill and entail no responsibility cannot be sold at professional prices, and it should not be a matter of surprise, if such prices are demanded, that business men step in and sell them according to business methods. The two departments must be kept quite distinct if the public is to recognise the professional side of pharmacy. But the public is perhaps beginning to understand that there is such a side, for in cases of serious illness most people prefer to have their medicine dispensed by firms whose reputation as accurate and conscientious dispensers is unquestioned rather than at stores. If the public has not yet learned that there is as much difference in the qualities of drugs as there is in the quality of tea, coffee, and other groceries it is the fault of the druggist for not pointing it out and proving that those who sell cheaply must necessarily buy cheaply, since a business man is not likely to sell the best article at the price of the lowest and try to live by the loss. So long, however, as the Pharmacy Act of 1868 continues in operation it is almost impossible for the pharmacist to divorce his business and his profession. He is faced by the position that the Government requires from the pharmacist, for the safety of the public, an expensive and tedious course of study before he can legally acquire the title of "chemist and druggist" and before he can supply certain scheduled poisons to the public, although he may rarely see a prescription, and other traders can sell other poisons, equally fatal and more frequently used, such as carbolic acid. Those, therefore, who live in districts where the business obtainable partakes more of the nature of that of a general dealer in chemical substances used for technical, agricultural, or horticultural purposes, and involving no personal responsibility, only pass the qualifying examination because they are obliged to do so by law, not because the knowledge of dispensing is of much use to them. This class forms probably at least three-quarters of those engaged in business as chemists and druggists, especially in the more populous centres in the Midlands and North of England. What they most need is a commercial education, instructing them in business methods and modern requirements. This has not hitherto formed part of a pharmacist's education and therefore the importance of the course of commercial education which has been started in some of our universities, and already forms an optional subject in the Philadelphia College of Pharmacy, cannot be over-estimated—at all events, for those chemists and druggists who have to depend chiefly upon the sale of miscellaneous chemical and other articles rather than on dispensing. The conditions which have hitherto obtained in the retail trade of chemists and druggists have not during the last 50 years been favourable for acquiring a useful knowledge of business methods, and such knowledge has undoubtedly in some cases been sought in a practical form at coöperative stores in the same way that Germans come to this country to learn English methods of business and then use them against us. The stores have, at all events, served a good purpose in tending to cause coöperation among chemists themselves. Coöperation can only be successfully met by coöperation, and when competition has lowered profits to a point at which it is impossible to live the natural reaction is bound to follow in the form of combinations or trusts to keep up the price to a remunerative ratio. This has been manifested already in connexion with the paraffin oil and cotton thread industries and iodine, and the P.A.T.A represents a step in the same direction.

[1] Proprietary Articles Trade Association.

THE FUTURE OF PHARMACY.

The history of the closing century indicates that scientific progress may be expected to be increasingly rapid in the coming one. As each new theory opens up new roads of discovery new trades will follow, or a differentiation of old ones. The pharmacist or dispenser of medicine will probably find enough to do in connexion with new synthetical products, proprietary articles requiring knowledge and skill, and new medical appliances. The chemist and druggist will find that he must keep pace with discoveries in chemistry and the technical uses of new chemicals, and will learn to realise the meaning of Playfair's maxim, that the competition of industries is the competition of intellect.

As the science of sanitation increases, and the laws of health become better known, demands for antiseptics and preservatives of all kinds, both for public and domestic purposes, are certain to increase, and the time may come when liquid air or liquid oxygen will be as commonly sold for sanitary purposes as potassium permanganate is at the present day. The study of animal chemistry, as yet in its infancy, may lead to the preparation of foods that will involve no waste of energy in digestion, and in combining the maximum of nutrition with the minimum of space. The immense importance of such concentrated food for travellers and for armies engaged in districts where transport is difficult may be easily conceived. The investigation of cellulose and protoplasm will probably reveal to chemists the methods by which gum, wax, fats, oil, starch, and even alkaloids and glucosides, are formed by plants, and before another century is over it may be as easy to obtain artificially by chemical means all these important commercial products from sawdust as it is to prepare glucose at present.

The knowledge that bacteria and ferments can produce substances which result in their own destruction will probably be carried out to its logical conclusion, until for all diseases resulting from these causes appropriate antidotes will probably be discovered and kept in stock by the pharmacist, by whom means of preserving them in active condition for a definite time will have to be discovered. The study of the healthy glandular secretions of the human body as remedies in disease will almost certainly lead to a study of the chemical processes by which they are formed, and the attempt to produce them artificially. This, again, may possibly be followed by an investigation of the nervous stimuli under which they are produced in nature, and to the properties of the nerve force which causes the secretion of the various fluids produced by the glandular system for the reparation of bodily waste.

Another and far-reaching object of research may be the scientific investigation of the inter-relationship of mind and body, the possibility of disease being caused and cured through the mind or by the power of the will to control the supply of nervous force to the various organs of the body. Possibly many of the diseases attendant on lowered vitality might thus be successfully combated. A study of the laws regulating the curious phenomena of idiosyncrasy, which is one of the greatest hindrances to the scientifically accurate treatment of disease, may lead to the possibility of preventing it or curing it at an early stage by hypnotic

suggestion or other means. But whatever discoveries the future may have in store the existence of the pharmacist will in any case depend upon the power of accommodating himself to new conditions and his ability to turn to practical account the very latest discoveries in science.

ADDISON'S DISEASE AND LEUCODERMA.

BY SIR SAMUEL WILKS, BART., M.D. LOND., F.R.S.,
PHYSICIAN EXTRAORDINARY TO HER MAJESTY THE QUEEN; CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

IN a lecture lately given at the Medical Graduates' College and Polyclinic by Sir William Gairdner, amongst other subjects said that he wished to say something about the connexion of leucoderma with Addison's disease. He spoke as follows, taking only the points at issue: "Possibly some of you may, and others may not, recollect a very early instance of this association which is of some historical interest. It is in Dr. Addison's famous monograph on Disease of the Suprarenal Capsule. I show you here the book and the plate. It is an evident case of leucoderma which Addison himself at least must have included in the book because he thought it was a case of disease of the suprarenal capsules. But, unfortunately, he had not a post mortem in this particular case. It is curious that Dr. Wilks, writing in Reynolds's 'System of Medicine,' puts his finger on this case and says because it was of a leucodermic order it is not a true case of Addison's disease. In short, he disputes Addison's own view of it. Now a good many years ago I had a case sent to me very late in the disease, when the patient was extremely ill, for an opinion. It was to my mind a case of Addison's disease, with pigmentation, largely of the usual Addisonian type but interspersed with circular and sometimes coalescent patches of vitiligo. That opinion I maintained until the patient's death. A post-mortem examination showed the usual form of disease of the suprarenal capsules. Dr. McCall Anderson, who had seen the case at an early period, had 'spotted' it as a case of leucoderma, but I do not know whether at that time he had made up his mind that there was any sufficient evidence of Addison's disease. However, the case is published in his book." "Not long after this the International Medical Association met in London in 1881 and Dr. Headland Greenhow read a most elaborate paper upon Addison's disease, and you all know how careful Dr. Greenhow was, not only as an observer, but as an almost exhaustive commentator on the literature of a subject. In reference to Addison's disease he may be said to have left almost nothing unnoticed up to the date of his research which is now published in a volume accessible to most of you. At the end of the paper I raised a question and stated briefly the leading facts of the case just referred to which had not at that time been published. I brought forward no theory, but thought the opportunity was a favourable one for ascertaining if anybody else at home or abroad had anything to say on the matter. We got no response. I alluded to the fact of Dr. Wilks having differed from Dr. Addison himself about the significance of leucoderma, as shown in Dr. Addison's own book, and suggested that it was a point requiring to be more carefully dealt with. But there was no information forthcoming and therefore we are bound to assume that no one there present (and it was a large assemblage) had anything to show. I have not seen many cases, but I have seen two or three more or less suggestive of the same thing and I happen to have at this particular time one such case under my care."

I should now like to say something with reference to these remarks of Sir William Gairdner which I think places the subject in a somewhat different position from that in which he sets it forth. I should like to take the opportunity of repudiating altogether the suggestion which some of my friends have made that I had any share in Dr. Addison's work. He was entirely original in his observations and I did no more than that which every pupil does, collect the cases, get the drawings made, and help the publication. This small participation, however, gave me special opportunities for continuing the work. During the next three years several fresh cases came under my notice and then I discovered how unique the disease was, that the change in the capsules was of one uniform kind, and that the discolouration of the skin also had its special characters. The malady, it may well be surmised, was a constant subject of conversation and I may here state that Dr. Greenhow was a frequent attendant in Dr. Addison's wards and acquired knowledge of Addison's views. I then placed all the new cases together, showed what three years had done in defining our knowledge, and in that paper repudiated the case of vitiligo. Before publication I showed my paper containing this repudiation to Dr. Addison. He returned it without comment, but wished me to publish it.

This paper was published in the Guy's Hospital Reports for 1859. I therein say: "As regards the character of the colour when it occurs the observation of several instances since the publication of the original memoir has shown that very great similarity has existed in all of them both as regards the colour itself and its method of affecting the body by a uniform implication of the whole surface. It is true that a case is represented [in Dr. Addison's work] where the body is covered with patches of colour chequered with white, but here no post-mortem took place to verify the diagnosis, and thus the fact is left as we state, that in the first related cases as well as in all subsequent ones there has existed a uniform discolouration of the whole integument. So remarkable has this been that the body has presented the appearance of a person with dark blood rather than that of a European and therefore the answer which Dr. Addison continually makes to interrogatories respecting the peculiarity of the discolouration is that he regards only those cases as characteristic where the surface of the body is seen to be gradually approaching in colour that of an inhabitant of some southern nation."

After another three years I had collected several new cases and wrote a second paper for the Guy's Hospital Reports for 1862. In this I reiterated my statement as to the uniform character of the disease. I say: "My principal object in bringing the subject before the profession is not only to strengthen the original facts by fresh instances but to point out how Addison had somewhat overstepped his own boundaries by including amongst his own cases some which did not present the true features of the disease and thus I hope, by purging his treatise of these examples, to place this remarkable affection on a much surer basis than it has hitherto had. The disease, indeed, will have more unique and special characters of its own and may be regarded with more justice in the light of a true discovery than Addison himself conceived and even more worthy to be honoured with his name than would a disease having the undefined nature which he himself assigned to it. I may at once admit that this want of definition and precision as to its true pathological character has constituted the great hindrance to the progress of the discovery; the belief of Addison being at the time of the publication of this work that any disease which affected the integrity of the suprarenal capsule would be attended by the remarkable phenomena which he described, and consequently his cases include a variety of morbid conditions of these organs which are clearly not true forms of the disease, and Addison, I believe, was beginning to see the truth of what is now evident that some of the cases which he had published have only stood in the way of the full development of his discovery, for all subsequent observations have shown that, so far from his early conclusions being correct, we have no recorded instance of the affection being connected with cancer, or, indeed, with any other kind of disease of the organ than the one which was found in the genuine cases which he first described, and which all subsequent experience has shown to constitute the true form of the malady. Unfortunately, too, Addison had placed in his work the drawing of a patient of whom no necropsy was made to reveal the true nature of the disease and that illustration has in all probability misled many by giving a false representation of the usual character of the discolouration of the skin.

"If these doubtful cases be eliminated from Addison's list there remain five which constitute a sufficient basis for his conclusions. I might say, also, that these were his early ones and those on which his own opinions were formed; it is therefore to be lamented that in the ardour of a fresh discovery he was led to include cases of which he had no opportunity of proving their genuineness. Fortunately for myself I was well acquainted with all the cases which Dr. Addison describes and have also had the opportunity of examining every subsequent example of it which has occurred in Guy's Hospital as well as seeing and discussing with the late lamented

physician many of his private cases, and I know, had he been spared to bring before the profession another edition of his work, he would have cropped his pages of those doubtful instances which have done much to retard the spread of the discovery. I may say, also, that Dr. Addison was in the habit of submitting to me all the specimens which he was constantly receiving from various parts of the country taken from patients who were supposed to have suffered from the affection bearing his name." "In clearing the ground of some of the extraneous matters which Addison introduced into his work the subject will stand much as I believe the author himself would have understood it at the time of his death."

I will now make a few remarks on these two positive statements, made many years ago, with regard to the uniform staining of the skin and the one disease only of the adrenal bodies—statements which have been reiterated by me on many occasions since. As regards the changes in the capsules it has always been surprising to me that anyone who has any knowledge of pathological processes should doubt my position. These changes, which may be in slow progress for years, must have their origin in the capsules themselves and cannot be due to any accidental affection which may alight upon them. The suprarenal disease, therefore, resembles in this respect the primary diseases of other organs, such as phthisis, cirrhosis of the liver, or Bright's disease. In these affections beginning from within there are certain symptoms due to the gradual impairment of the functions of the organ and we never think of looking for these symptoms if the organs have been accidentally attacked by a cancerous growth or hydatid. This shows how crude Dr. Addison's views must have been to have inserted a case of cancer because there was also present some discolouration of the axilla. I was in the habit of describing the true disease as one of inflammation of both capsules causing the production of an albuminous matter which subsequently softened or became cretaceous, and often ending in the disappearance of the organ, such as is sometimes seen in a lymphatic gland or the thyroid body. Before bacterial times we often called these cheesy organs "scrofulous" or "tuberculous." When I speak of this disease of the capsules as primary I include those cases where the inflammatory process has proceeded from caries of the spine.

And now I will state how the matter stands. Dr. Addison taught in his oral discourses that the discolouration of the skin was uniform and he was in the habit of saying that it could not be distinguished from that of a person of dark blood; he never said a word about white patches or vitiligo. I confess it is remarkable in a man of his scientific accuracy that he should have allowed himself to have inserted the case of leucoderma when it was brought before his notice by a man who had only a superficial knowledge of the disease which Addison had discovered. After the publication of his memoir the author continued to teach as heretofore, never saying a word about leucoderma, and when, as I have before stated, I showed him my paper objecting to the case he acquiesced in its publication. What I then said I have reiterated on numerous occasions for nearly half a century, during which time many cases of leucoderma have been sent me as supposed examples of Addison's disease. In no single case has this proved to be true.

Again, Sir William Gairdner speaks of the exhaustive treatise of Dr. Greenhow, written 25 years after Dr. Addison's first memoir, and says that the author makes no mention of leucoderma. What does he infer from this? Now with all this evidence of a remarkably uniform kind of 50 years I have referred to me a case which Sir William Gairdner on more than one occasion has mentioned as opposed to the doctrine which I have all my life maintained. I hold myself open to correction if there be other instances, but the only one to which he referred me and the hearers of his lecture was that which he saw in consultation with Dr. McCall Anderson and could be found in the work of the latter author. It is a pity that the case was not a more striking one for Sir William Gairdner's purpose and as accurately reported as the large series of cases which have hitherto come before me. In his case I do not understand that the patient was covered over his body with white patches as in Addison's drawing, for the history only speaks of the spots on the arms and backs of the hands, which parts had previously been the subject of eczema. Then, again, I consider the description of the capsules is very obscure, and as regards other organs it says: "*Kidneys.*—Both had the character of the large white kidney of Bright." Now Sir William Gairdner will surely agree with me that there is no exception to a law of nature and that the apparent exception must be explained by the discovering other circumstances operating to cause the peculiar result. Now I will not say that the statement I have made as to the nature of Addison's disease constitutes a similar law, but when the same clinical and pathological fact has been observed in thousands of cases without exception during a long series of years I do not think he will charge me with shuffling out of a difficulty when I criticise fully his adverse case and suggest that it is not a clear example of Addison's disease combined with leucoderma. The skin affection is not well described nor is the state of the capsules, and, moreover, the patient was the subject of Bright's disease—another novelty, as I do not remember in other cases to have found any disease but occasional phthisis. I feel sure that so philosophic a man as Sir William Gairdner could not wish me to accept on his authority so poor and obscure a case. Indeed, I should not have troubled the profession with this long communication had not the subject been brought before a society in London by the leading physician in Great Britain.

Grosvenor-street, W.

CARBOHYDRATES AND DISEASE.

BY ERIC PRITCHARD, M.A., M.D. OXON.,
AND
E. H. COLBECK, B.A., M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

THE health of all living organisms is determined by two factors—firstly, by their environment, and secondly, by their inherent vitality, or in other words by their capacity to react to stimuli engendered by that environment. Disease, on the other hand, occurs through failure on the part of the organism to accommodate itself to its surroundings, or, otherwise expressed, because the stimuli are excessive, sub-minimal, or absent. Health or disease are therefore determined by the ratio between the stimuli and the power of the organism to respond. The environment may be considered to include all material that can be classed as food, such as solids, liquids, and gases which contain the chemical elements, or groups of elements, necessary for metabolism, and all those physical stimuli, such as heat, light, &c., which are requisite to set the metabolism in motion.

In a complex multicellular organism such as the human body, under the central administration of the nervous system, accommodation to its surroundings is effected in a manner which, from the standpoint of physiological economy, is most advantageous to the individual as a whole, and through its agency the tissues are mutually enabled to coöperate, and in times of stress to afford reciprocal assistance the one to the other. For instance, should the food-supply fail the coördinated action of the central nervous system will administer to the wants of the more vital organs at the expense of those which subserve less important functions; and, on the other hand, in the presence of excess will effect the disposal of those portions which are unnecessary for the performance of useful functions in a manner least inimical to its general well-being. Through want of more complete knowledge it is impossible to predict in any given case what method or methods the organism will adopt to secure the removal of material which it does not require, but reliance may be placed on its perspicuity to select the path of least physiological resistance and that which in its ultimate operations is most conducive to the maintenance of life. The following is an incomplete summary of the more usual methods on which the organism relies for the disposal of supplies which are not requisite for ordinary physiological purposes. 1. Complete metabolism by the tissues, with removal by the excretory organs (luxus consumption). 2. Loss of appetite, vomiting, diarrhœa, and protective coating of the absorbing surfaces with excess of mucus. 3. The metabolism of the food into incompletely oxidised end products and their removal from the body with more or less detriment to the organism. 4. Growth of normal tissues (hypertrophy), and growth of degenerate tissues (mucoid, amyloid, adepoid), new growths (tumours,

granulations), and leucocytosis. 5. Loss of tissues, discharges (purulent, mucous, serous, &c.), and hæmorrhage. 6. Active metabolism with the production of heat (fevers). 7. Development of kinetic energy, restlessness, spasms (tonic and clonic). 8. Parasites. An attempt to deal with these various methods would necessitate a review of the whole domain of medicine. We propose, therefore, in the present paper to confine ourselves solely to the method which is included in Group 3—that is to say, the disposal of excess of circulating material through more or less incomplete metabolism by the tissues; the removal of the incompletely metabolised end products involves certain pathological consequences, which we propose in due course to examine.

The living proteid molecule (biogen), into which highly complex body all assimilated food is ultimately resolved, undergoes, as an expression of its restless vitality, continuous explosive metabolism, whereby atomic groups, more or less simple in character, are discharged from the primary nucleus and oxidised in the presence of oxygen with the liberation of energy. The cleavage products are replaced by corresponding or equivalent elements from the surrounding nutrient media. Under favourable conditions the atomic groups which are thus shed by the biogen molecule consist partly or chiefly of the ultimate metabolites, carbonic acid, ammonia and water, which for purposes of safe removal from the system are further combined into urea (a practically harmless amido-acid) and carbonates, the bases for which are obtained from the circulating tissue juices and the blood. Such an ideal result is, however, seldom obtained; the biogen molecule from want of a sufficiency of oxygen, or from deficient vitality, parts with larger atomic groups than carbonic acid, ammonia, and water, and such bodies as glucose, lactic acid, glycolic acid, oxybutyric acid, acetic acid, propionic and formic acids may under these circumstances be produced. It is still a matter of uncertainty whether these bodies are cast off in their complete form from the biogen molecule or whether they are partly the result of synthetic processes. In any event the sum total of the energy liberated will depend rather on the nature and size of the atomic groups than on the method of their production.

From a physiological and economic standpoint it is difficult to define precisely whether the cleavage of large atomic groups is a conservative or a wasteful process; but presumably, when there is no demand for energy, as, for instance, in an overfed and underworked individual, it is a conservative method; or otherwise, with the complete combustion which goes hand in hand with the liberation of the final end products, carbonic acid, ammonia, and water, there would be a great development of heat and possibly that condition of hyperpyrexia which is characteristic of the riotous metabolism of certain cases of fever. On the other hand, with the development of useful energy, such as occurs when the voluntary muscles are brought into play, and when the oxygen supply is at its maximum, owing to the harmonious coöperation of the circulatory and respiratory systems, it is probable that the biogen molecule extracts to the uttermost unit the energy supplied by the circulating media, or by its own substance, and by a process of rigid economy parts with atomic groups, such as carbonic acid, ammonia, and water, which in a physiological sense are inert and useless bodies from which no further energy can be extracted. At present, however, we are concerned with the cleavage from the biogen molecule of the larger atomic groups such as occurs with deficiency or absence of oxygen—namely, dextrose, lactic acid, and allied bodies. Dextrose, as is well known, may be removed by the kidney without further change, and its presence in the urine is associated with the condition known as diabetes. With regard, however, to the acid products of metabolism it must be remembered that the circulation refuses to deal with such bodies without neutralisation, and hence their affinities for bases must be satisfied at the expense of the potassium or sodium circulating in the blood or tissue juices, or at the expense of the ammonia, which is concomitantly liberated in the act of metabolism. As a matter of fact, the neutralisation appears mainly to be effected by the substitution, in the acid molecule, of one (NH_2) group for one atom of hydrogen with the formation of amido-acids, such as glycocine (amido-acetic), tyrosin (amido-oxy-phenyl-propionic), leucin (amido-caproic), sarcosin (methyl-amido-acetic), cystin (amido-lactic in which one atom of H is replaced by HS), and uric acid (possibly by various methods). The amido-acids are bodies of the nature of weak bases, and they can be removed by the excretory organs without serious consequences. We cannot here discuss the question whether these amido acids are formed *in situ*, or whether the free acids are neutralised by bases (such as Na, K, NH_4) and subsequently converted elsewhere into amido-acids, but in any event the question does not affect the argument of this paper.

Now, the formation of harmless amido-acids out of noxious free acids creates a demand for nitrogen or ammonia, which the biogen molecule may be unable to spare, for of all elements nitrogen is the most essential to the living proteid molecule; and should it be unable from failure in the supply to obtain enough from outside sources its very existence may be jeopardised; hence, instead of parting with (NH_2) for the neutralisation of the free acids, this radicle may be again taken up into the original biogen molecule to form, in conjunction with material taken from the floating supply of carbohydrate, new protoplasmic substances. The amount of nitrogen which can be spared from the biogen molecule must be dependent on the floating supply of nitrogen containing foods; hence we may sum up the position by saying that the formation of harmless amido-acids out of noxious free acids is dependent on an adequate supply of nitrogen-containing food.

There is now the further case to consider of an excess in the floating reserve of nitrogen-containing elements as compared with those that are nitrogen-free. In such an event there will be no difficulty in supplying (NH_2) radicles for the neutralisation of the acid products, but rather a demand for carbon, or carbon-containing groups, to satisfy the affinities of the free ammonia. Under these circumstances we should expect to find a tendency for the production of bodies in which the relative proportions of carbon and nitrogen were more or less evenly balanced, and, as a matter of fact, that is exactly what takes place when there is an excessive ingestion of nitrogenous food, for the following bodies are found in the urine: uric acid ($C_5H_4N_4O_3$), xanthin ($C_5H_4N_4O_2$), guanin ($C_5H_5N_5O$), creatin ($C_4H_9N_3O_2$), and creatinin ($C_4H_7N_3O$).

We may therefore say that, with defective metabolic and oxidative processes, large atomic groups are shed from the biogen molecule, which contain no nitrogen (free acids, such as lactic and glycolic), a small quantity (amido-acids), or a large quantity (uric acid, guanin, xanthin, &c.), according as the nitrogenous diet compared to the non-nitrogenous is deficient, moderate, or excessive. Hence it follows that, under like conditions of metabolism, an absolute or relative excess of non-nitrogenous material (carbohydrates) as compared with nitrogenous (proteid) will promote the formation of free acids such as lactic acid, &c., which after neutralisation will be set free in the circulation.

The group of symptoms associated with the defective metabolism of nitrogen-containing bodies has long been known as gout or lithæmia; the group of symptoms associated with the defective metabolism of non-nitrogenous substances has been dignified by no special title, except in the extreme cases of glycosuria and diabetes. It seems, however, hardly logical to suppose that an organism which is phylogenetically to a large extent carnivorous should be the victim of symptoms and diseases which are exclusively due to the defective metabolism of food by nature intended for its consumption, and that it should be immune from symptoms, however much it may trespass on the food domain of the herbivora.

We propose now to investigate the symptoms which may arise through the defective metabolism of non-nitrogenous material and to take up the history of the cleavage products from the point at which we left them—namely, waiting for neutralisation and removal at the seat of production. Now it is quite clear that if these bodies are not neutralised by ammonia to form amido-acids, or salts of ammonium, they cannot with physiological safety be removed in the condition of free acids; hence as expeditiously as possible they seize hold of such bases as sodium or potassium from the circulating media and satisfy their affinities at the expense of neutral or alkaline salts. Thus neutralised they can enter the circulation, which is itself reduced in alkalinity, in direct proportion to the amount of bases taken up by the acids. After they have effected an entrance into the circulation these neutral bodies can travel here and there until they meet with suitable conditions for their removal. We propose to take the lactates as representing a type of the various salts, which we have shown are a sequence

of excessive carbohydrate metabolism, since it is impossible to follow each in its more or less similar path of excretion.

The kidney, which is *par excellence* the excretory organ of nitrogenous refuse, does not appear to play any important part in the removal of lactates from the system, for they are seldom found in the urine, although the blood normally contains an appreciable, and at times an excessive percentage. Active glands, such as the liver and spleen, and those of the skin and mucous membranes, are probably the situations in which these products are most effectively dealt with. The skin is particularly active when the muscles are contributing a large proportion of free acids, and at times (rheumatic fever) free lactic acid has been detected in the sweat. Both in this situation and elsewhere, when metabolism is active and the oxygen supply is abundant, the lactates are oxidised to carbonic acid and water, and at the lung surface with a copious secretion of mucus various representatives of the series are found in the condition of free acids. Lactic acid is so frequently detected in the gastric juice that it is reasonable to suppose that its origin is the blood stream, and not decomposing ingesta. Such, then, are the normal methods whereby the excretory processes keep pace with the supply. Nevertheless, should any important excretory agency, as, for instance, the skin, be thrown out of action, and fail to take its share in the process of elimination there will be a proportionate increase of strain on those organs which remain to do the work. The more slowly lactates are burnt off the greater will be the accumulation in the circulation and the lower the alkalinity of the blood and tissue juices; free acids will with difficulty be neutralised, and the strain on all internal organs will become increasingly severe as the vicious circle of events extends more and more widely. Under such conditions signs of breakdown or failure may be evidenced in those organs or tissues which are functionally least able to meet the difficulties. Fibrous tissues may become inflamed and mucous surfaces hyperæmic and catarrhal. The system in its efforts to rid itself of potential sources of dangerous metabolites may hastily improvise and cast off in their entirety large quantities of emasculated protoplasm, such as mucin, which is a hybrid proteid containing a large proportion of carbohydrate. In this connexion it is deserving of consideration whether iodine and iodides, owing to their capacity for bringing mucin and mucinoid bodies into a state of solubility in the system, may not have important bearings on the treatment of such diseases (myxœdema, &c.) as may be due to the clogging of the tissues by this compound carbohydrate. In any case there is ample clinical evidence to show that iodine and its salts act as powerful eliminants.

For purposes of illustration we shall now take the hypothetical case of an organism, such as the human body, hampered with excess of carbohydrates—a condition which we propose to call "glycosachthæmia" [γλυκός (sweet), σακτός (crammed), and αἷμα (blood)]—and follow in detail the means that will be employed to get rid of this superfluity of food, and the symptoms that will be produced in the process of its removal. For the sake of convenience we propose to take first the case of young and growing tissues, since, under these conditions, vitality will be at its maximum, and we should expect, therefore, that the difficulties of dealing with an excess of food would be most effectually overcome. We should be prepared to find that an infant, given opportunities of absorbing an excess of carbohydrates from the alimentary tract, would, after satisfying the present needs of growth, activity, and heat production, first store the surplus in the liver and other tissues in the form of a reserve material (glycogen). So soon as storage in this direction has reached its physiological limit the excess of circulating carbohydrate would be laid up in the form of a more or less degenerate tissue (such as fat), or would be excreted after complete or incomplete metabolism. The more nearly the physiological limit of fat deposition is approached the greater would be the amount of circulating carbohydrate, and hence the larger would be the sum total of the end or intermediate products derived from its metabolism. We have previously shown that with deficiency in the supply of oxygen (determined by respiratory, circulatory, and hygienic conditions) there is an increase in the proportion of the intermediate end products (in the form of lactic acid, glycolic acid, &c.) as opposed to normal end products, and *ceteris paribus* with a deficiency of NH_3 (consequent on an insufficient supply of floating proteid) there is an increase in the proportion of these products (in the form of free acids) let loose in the circulation. In an infant, therefore, who is absorbing a large excess of carbohydrates (a process that is facilitated by the solubility of these substances), and in the absence of an adequate supply of oxygen, as well as of proteid (proteid is not readily digested and absorbed by infants), we should expect to find an excess of lactic acid (in the form of lactates) and other acids (in the form of salts) in the system. Moreover, if this excess of lactic acid, &c., be admitted we should expect to find evidence of some attempt on the part of the organism to get rid of it. We should anticipate, therefore, hyperæmia and enlargement of the liver and presumably of the spleen. The skin should show evidence of activity in the form of free perspiration; and should this large and important metabolic surface be thrown out of action (by chill, &c.) we should be prepared to find that a more severe strain is thrown on the other tissues which have been coöperating in the oxidation and elimination of the end products of the carbohydrate metabolism. The mucous membranes would show signs of strain by excessive hyperæmia and mucous secretion, and this would be shown clinically by attacks of bronchitis, pharyngitis, tonsillitis, enteritis, colitis, &c. The liver and spleen would exhibit additional hyperæmia and enlargement. The epiphyses of bone, centres of enormous protoplasmic activity in infancy, would become hyperæmic, and the thymus and lymph glands might share in the general increase of vicarious metabolism. When the increase of excretory activity, as evidenced by the hyperæmia of the tissues which we have mentioned, with the coöperation of a deficient supply of oxygen, fails to keep pace with the supply of the circulating end and intermediate products of carbohydrate metabolism, signs of irritation should be demonstrable in the nervous system in the shape of irritability, restlessness, and convulsions, &c. The muscular system should be inactive and flabby from what is tantamount to the condition produced by fatigue. Fever would be present from excessive metabolism, and those micro-organisms which live upon saccharine substances might find a nidus on the free mucous surfaces (thrush). So far as the fibrous tissues are concerned we should expect some hyperæmia which in the young and growing condition of these structures would be sufficient to enable them to cope with the local difficulties of metabolism, and these, by nervous coördination, would not be of a severe kind. As the glycosachthæmic infant in due course develops into the child, with the evolution of the muscles of locomotion and the concomitant stimuli to the circulatory and respiratory systems, which this change engenders, we should expect to find evidence of a general abatement of the symptoms. At the same time the gross improvement must be somewhat discounted by the general but gradual fall in protoplasmic activity, which throughout the body bears, roughly speaking, an inverse ratio to the age of the individual. In consequence of the defective ossification of the skeletal system which has been brought about by the continued hyperæmia of the active epiphyses (compare Kassowitz's experiments) with lowered alkalinity, and possibly occasional acidity of the surrounding tissue juices, we should expect to find gross modifications in the morphological structure of the osseous tissues in accordance with the mechanical strain exerted upon them by the muscles and body weight. Furthermore, we should expect to get enlargement of the epiphysial ends of the bones. For similar reasons the teeth will late assume that degree of calcification which is necessary for their irruption through the gums and the permanent teeth will show structural modification and may eventually become carious. The fibrous structures, owing to the proliferation of cells which is the physiological sequence of hyper-nutrition and minimal irritation during the active period of their growth, will show signs of laxness and stretching. The joints will be inadequately supported and later there may be signs of fibrosis where growth is almost at a standstill, where the circulation is most feeble, and where there is exposure to pressure or injury (fibrous nodules in the neighbourhood of bones and joints, nodules in the endocardium, and cardiac valves). The capsule of the eyeball and the suspensory ligament would share in the general laxity of the fibrous structures, and herein may lie the explanation of the myopia so often observed in rickety and unhealthy children. The connective tissue of mucous membranes long subject to catarrh may

show evidence of extensive thickening (adenoids, &c.). The nervous system may give way under the long-continued strain, and choreic symptoms, consequent on cerebral irritation, may develop. Moreover, the fibrous lining of the cranial cavity and membranous envelopes of the brain may, along with other fibrous structures, show signs of undue irritation (meningitis). During the early period of childhood chill to the integuments will intensify the symptoms due to the irritation of internal organs and develop acute catarrhs and fevers. As adolescence is reached and passed with concomitant cessation of active growth, the tissues will be less able to deal with the excessive nutriment which is the characteristic feature of the glycosachthæmic condition. Unless, therefore, the muscular system comes into active coöperation with the other excretory organs those tissues will suffer which are least able to cope with the excessive supply of nutriment and the intermediate end products of partial carbohydrate metabolism. We should now expect the fibrous tissues to give early evidence of their inability to deal effectively with these imperfect metabolites. Minimal irritation, which in the case of their embryonic, or young and growing antecedents produced proliferation of cells and increase of growth, now necessitates the adventitious assistance of leucocytes. By positive chemotaxis the migration of white cells may be determined, or, in other words, inflammation produced. Chill will now produce the symptoms of acute inflammation of the fibrous tissues of the joints, endocardium, and other parts, with the development of high temperature. Moreover, there seems no reason why the pyrexia which arises under these circumstances and the vicious habits of metabolism thus engendered should not continue until the combustion of the stored-up carbohydrate material is complete and the end products eliminated from the system. Furthermore, the duration of the fever cannot be measured by the period requisite to get rid of the carbohydrate material only, since the proteid and hydrocarbon foodstuffs (both floating and fixed) must of necessity share in the oxidative processes and thus by saving carbohydrate metabolism prolong the course of the fever. Moreover, in accordance with the recognised dietetic treatment of fever, additional fuel for combustion is provided with unfailing regularity. Again, under the circumstances which we are considering we should expect that occasionally, as the result of long-continued strain or diminished vitality, the synthetic processes connected with catabolic metabolism would fail and the consequent riotous metabolism of the biogen molecule would give rise to hyperpyrexia. The more active the skin and mucous membranes the less will be the intensity of the symptoms due to hyperæmia or inflammation of other tissues. At the same time the skin and mucous membranes under continued stress of work will ultimately show signs of wear and tear. The skin will be hyperæmic and will show a tendency to the development of eruptions—i.e., erythema, purpura, eczema, psoriasis, acne, &c. The respiratory mucous membrane will give evidence of catarrhs (tonsillitis, bronchitis, asthma, pneumonia, &c.). The tongue will be furred and the stomach and intestines possibly coated with excess of mucus. The fibrous tissues of the joints, endocardium, &c., will become acutely inflamed, but we should expect that the endocardial tissues would suffer less than other fibrous structures, inasmuch as they are continuously bathed by a more or less alkaline fluid (the blood). The muscles will give evidence of debility or "fatigue." Hollow viscera will become dilated (the heart, &c.) and the skeletal muscles toneless and weak. The nervous system may develop signs of instability (neurasthenia or even neuritis, epilepsy, &c.). The more chronic manifestations of the glycosachthæmic condition in adult life would be skin eruptions in the form of psoriasis, erythema, acne, eczema, &c. Inflammatory conditions of the respiratory system of a sub-acute type, such as tonsillitis, bronchitis, asthma, &c., would be of common occurrence. We should also expect chronic inflammatory conditions of the fibrous tissues surrounding the joints and other parts. In debilitated conditions glycosuria might possibly occur. With the advent of late middle life and old age when metabolic processes become less and less active, and when in consequence of the hampered condition of the respiratory and circulatory systems oxygen with difficulty reaches the tissues, the biogen molecule may cast off even larger atomic groupings than lactic, glycolic, and similar acids. Under these circumstances glucose and acetone may be shed in their entirety. A strain is doubtless thrown upon the kidneys, but the organism may be temporarily spared for the continuance of a useful existence. Owing to the inhibition of oxidative and catabolic processes the temperature would be low until such time as, in the general break-up of the tissues, chemical affinities are loosened with the liberation of energy in the form of heat and the ultimate destruction of the organism as a corporate body. Before this stage is reached the general interference with nutrition would provoke a more or less widespread degeneration of the tissues, and the possible growth in various organs of micro-organisms which thrive in a saccharine medium.

The hypothetical pictures that we have drawn of the general condition of glycosachthæmia during the various stages of infancy, childhood, middle life, and old age are practically those of the clinical conditions known as rickets, the rheumatic state of childhood, rheumatism, and diabetes; and although, viewing the matter from the standpoint of established facts, it is not always easy to prove that the one condition is an antecedent of the others, nevertheless there is a certain amount of evidence to show that such an assumption is reasonable, and the evidence that we have so far obtained is entirely in harmony with this view. In the case of rickets it is nearly always easy to prove that there has been a great excess of carbohydrate food, and although in the case of rheumatism and diabetes it is easy enough to shelter oneself behind a plea of relative excess, on inquiry it is usually possible to obtain evidence of carbohydrate indulgence which in many cases may be termed "gross." Rheumatic subjects, at any rate before the emaciating effects of defective circulation come into operation, are mostly well-nourished and often fat; and they are liable to exacerbations of the symptoms at times of forced inactivity, after periods of healthy energetic life, and when a good appetite remains to them, although its legitimate stimuli may be in abeyance. Soldiers proceeding on sea voyages, vigorous from regular exercise, are especially liable to attacks of rheumatism and pneumonia, and Londoners returning to town after their holidays nearly always contract a "cold." Athletes when they go out of training, unless they can physiologically protect themselves by a rapid deposition of fat, are liable to various ailments, such as may be readily explained by a condition of glycosachthæmia. Conversely, starving people rarely contract diseases of this type, and most striking evidence can be drawn from the present war in South Africa; in Ladysmith and Mafeking the semi-starved defenders were exposed in trenches half full of water to the sudden changes of temperature which characterise the autumn and winter months, yet rheumatism was conspicuous by its absence, especially towards the end of the period of siege when one may suppose their tissues were depleted of all carbohydrate reserve. In this respect the experiments by Araki[1] and Irisawa[2] in Hoppe Seyler's laboratory are of the utmost importance, for they have shown that in the case of animals lactic acid is produced in excess when the oxygen supply is curtailed, and that when the supply is minimal even dextrose may appear in the urine; but in the case of starving animals, however much the oxygen supply is reduced, no dextrose appears in the urine nor is the percentage of lactic acid in the blood increased.

Further evidence can be adduced from the field of therapeutics, for those measures which are known to be effective in the case of rickets, rheumatism, and diabetes are those which would be rationally prescribed for persons suffering from saturation with carbohydrates. Milk diet, or, in other words, semi-carbohydrate starvation, is the universal panacea for rickets and rheumatism, and in diabetes there is no more efficacious treatment. In chronic rheumatism our own experience, which is amply confirmed by others, goes to show that the effects of the "Salisbury treatment" (total carbohydrate starvation) are sometimes almost sensational in their efficacy. All those drugs which encourage the activity of the skin are of value in rickets, rheumatism, and diabetes. Purgatives by the rapid removal of ingested food are recognised as essential adjuncts to all lines of treatment, and alkalies hold a time-honoured position in the treatment of all these complaints.

[1] Zeitschrift für Physiologische Chemie, vol. xv., p. 335, and vol. xvi., p. 201. [2] Ibid., vol. xvii., p. 340.

By neutralising the acid products and thus assisting in their elimination their action is in harmony with our view. Salicylates above all drugs are specifics of rheumatism and are said to be useful in diabetes. We firmly believe that they are strongly indicated in rickets, though as yet we have had few opportunities of estimating their value. On our hypothesis they are of value in the treatment of rheumatism because they combine with that atomic group which in the break-up of the biogen molecule is a fore stage of lactic acid, glycocene, and perhaps other bodies.[3]

$$C_6H_4\begin{cases}OH\\COOH\end{cases} + CH_2\begin{cases}OH\\CN\end{cases} = C_6H_4\begin{cases}OH\\CNOH\\COOH\end{cases}$$
$$CH_2$$

Salicylic acid. Methene cyan-alcohol. Salicyluric acid.

They are of less value in diabetes because the entire dextrose molecule is separated from the biogen molecule and requires no neutralisation. They are of value in such cases by preventing the formation of certain by-products which are usually found in company with dextrose in the urine. With regard to the use of salicylates it must be remembered that the maximum effect is only obtained when they are given in large doses; large doses would obviously be required if our view is correct.

In the attempt which we have made to establish a causal connexion between excessive carbohydrate ingestion and the incidence of disease we have avoided for the most part making an appeal to the evidence derived from clinical experience. Our reason for this obvious omission is that our complete recognition of the essential features which underlie the theory which we have advanced, is of such recent growth that we have not yet had time to accumulate clinical testimony in sufficient amount to carry weight in support of our contention. Nevertheless, the observations which we have thus far been enabled to make on the clinical side of the subject are in complete harmony with the conditions which on theoretical grounds we should expect to obtain. Furthermore, we may point to the clinical experience of such keen and original observers as Rabagliati and Keith which lends strong support to the views which we have enunciated. Rabagliati gives convincing proofs of the evils which may be wrought by the over-ingestion of carbohydrates, and Keith, in his advocacy of the therapeutic efficacy of starvation (so-called) in the treatment of disease, supplies indirect evidence in support of our contentions.

Although we have endeavoured to clearly distinguish between the condition known as lithæmia or gout, and the one we have termed glycosachthæmia, we have not attempted to indicate the effects which might be produced by the possible action and interaction of their respective metabolites. That such reaction and inter-action between the metabolites of these conditions does take place there can be little doubt with the production of disease, which in its pathological significance combines in varying degrees the features common to lithæmia on the one hand and glycosachthæmia on the other.

Although it cannot be asserted that we have advanced any convincing proof of the existence of the condition which we have termed glycosachthæmia we venture to hope that the evidence which we have brought forward will serve to stimulate other observers to investigate the subject. For our own part we feel convinced that further inquiry will serve to strengthen the views which we have advanced in this paper and to establish the theory of glycosachthæmia on a firm foundation of fact.

BRENTRY HOME FOR INEBRIATES.—At the meeting of the Gloucestershire County Council held on July 10th it was reported that this home was now contributed to by 23 county and borough councils to the extent of £25,000. This involved a provision of 104 beds for women and 73 for men. When their arrangements were completed there would be 183 beds against the required 177. Up to the present 58 cases had been admitted.

CARDIFF INFIRMARY.—At a meeting of the Executive Committee of the Cardiff Infirmary, held on July 17th, it was decided to recommend to the governors of that institution that the appointment of general superintendent be vested in the resident medical officer and that the duties of the secretary be solely confined to secretarial and financial work.

THE WAR IN SOUTH AFRICA: JOTTINGS IN BURGHERSDORP.[1]

BY HERBERT CAIGER, M.B. LOND., F.R.C.S. ENG.

I WAS in Burghersdorp during the Boer occupation of the town and saw a number of the wounded after the battle of Stormberg.

THE BATTLE AT STORMBERG, DEC. 10TH, 1899.

At this battle General Gatacre's forces met with a serious defeat, losing 650 men as prisoners. About 70 of these prisoners were wounded and they passed through Burghersdorp on their way to Bloemfontein. 24 of them were kept at Burghersdorp for a month or more in an extemporised hospital arranged by the British residents at the request of the Free State authorities. Many of the wounds were trifling in nature, and 18 of these men marched 20 miles from Stormberg to Burghersdorp on the day following the battle and the remainder were brought to Burghersdorp by ox wagons at different dates. Half of these would be fit for service within a month. The transport by ox wagon was bitterly complained of, the jolting over the rough roads having caused much aggravation of painful wounds. One man's chest was blistered by the heat of the sun, the wagons being uncovered. The wounded officers were brought to Burghersdorp in covered carts. The wounded men spoke well of the treatment which they had received from their Dutch captors at Stormberg.

On the battlefield the men were attended by two medical men who went out from Burghersdorp on the chance of being of some use. The men were anxious to know whether they would be attended by English practitioners, and they were very pleased to hear that there were none but English medical men in Burghersdorp. The nursing in the hospital was done by English (male) residents and refugees from the Republics. The school building was used for the hospital and came to be used more or less as a club as most of the Englishmen of the place met there, as it was almost the only place, with the exception of the private houses, where it was considered safe to speak freely. The amateur male nurses worked well in watches of three hours at a time. There were but few cases which required skilled nursing. Lord Roberts subsequently wrote to the mayor of the town thanking the British residents of Burghersdorp for all that had been done for the wounded and prisoners who passed through the town.

An interesting cerebral case.—A private who had been shot through the head completely lost his memory of events preceding the battle. There was no paralysis. A Mauser bullet had entered at the outer end of the left eyebrow and had passed out on a level with the occipital protuberance about an inch to the left. When seen 10 days after the wound of entrance was perfectly healed and difficult to see. The exit wound was still covered by a small scab. He had a dazed look, and when asked questions would reply, "I cannot rightly mind that, sir." He remembered one thing in his past life. He said that he was married and that his wife was married too. This latter statement he is said to have reiterated again and again shortly after the battle. With this exception he remembered nothing of his past history, and did not regain his memory up to the time when he left for Bloemfontein, 40 days after the injury. His memory for events after the battle seemed to be fairly good.

Nerve injuries.—The men who seemed to suffer most and longest were those who had wounds involving nerve trunks. I had three of these patients under my care for several weeks, and it was sad to see the agonies they suffered. Morphia in large doses was the only thing that gave any relief to the pain. A sergeant had an oblique flesh wound of the thigh which healed by first intention, but pain came on about 14 days after the injury. He had had severe hæmorrhage immediately after receiving the wound which he stopped by means of an improvised tourniquet which was left on for 36 hours. Possibly this may have had something to do with the causation of the pain. The pain was felt in the outer side of the leg below the knee and in the toes. There was no evidence of any paralysis, and, indeed, the man had been up and about for several days before the pain

[1] An abstract of Dr. Herbert Caiger's article which appears in the August number of the Phonographic Record of Clinical Teaching and Medical Science.

came on. The pains continued for a long time and were still very severe when he wrote from Cape Town in April. No operation was done. In the two other cases there was marked paralysis and wasting of muscles. In one some cord of the brachial plexus was probably injured, and in the other the median and ulnar nerves were injured by a wound about the middle of the arm. In both these cases the pain came on on the day of the battle and was intense from the first. The operation in one of the cases was performed at Bloemfontein, and with relief to the pain.

Fatal mental disease following severe wounds.—An officer was wounded by shrapnel fired by our own artillery. The nature of the wounds necessitated amputation of one leg and some of the fingers of each hand; he had also several wounds of the trunk, and for some time was not expected to live. He recovered so far, however, that he was removed to the hospital at Burghersdorp some weeks after the battle. The wounds healed completely, but he continually brooded over the disaster at Stormberg, which troubled him much more than the mutilation he had suffered from, and at length he died from acute mania. Shortly before his death the Free State Government had granted his release in return for a wounded commandant who had lost one of his legs after the battle of Elandslaagte and was released by Lord Roberts. The officer was dying when the news of his release arrived and he could not be moved. His body was taken back to the British lines where he was buried by his comrades with military honours. This was the only death which occurred among the wounded prisoners who were brought back to Burghersdorp from the battle of Stormberg.

Septic cases.—The proportion of septic cases to the whole number of wounded was small. The worst case was a wound involving the mouth. The bullet entered at the angle of the mouth and passed backwards and slightly downwards, emerging at the back of the neck about an inch from the middle line. It had ploughed along the inside of the cheek, knocked out a lower molar, broken some fragments off the lower maxilla (which came away at a later date), and perforated the posterior wall of the pharynx. This man's mouth was in such a foul condition when he arrived at Burghersdorp, four days after the battle, that he had to be placed in a separate ward. After the separation of some very foul sloughs the mouth wounds healed, but he then developed a deep abscess in the sub-maxillary region. This was opened just before he left for Bloemfontein, nearly six weeks after the battle. Many of the wounds were inflicted by Martini-Henry bullets, and, of course, the wounds were more severe than those caused by Mauser bullets and a greater number of them suppurated. Many of the shrapnel wounds, on the other hand, remained quite aseptic. A compound fracture of the lower end of the ulna from a shrapnel bullet, which was under my care, did perfectly well.

PHYSIQUE OF THE BOERS.

I have had the experience of six years' practice among the Boers of the Jacobsdal and Burghersdorp districts, and am of opinion that in comparing the Boers with Tommy Atkins the advantage is on the side of Tommy. The Boers are more used to out-of-door life and irregular meals, they suffer less from syphilis, and they are more independent and more accustomed to act on their own responsibility, but, on the other hand, although the average age might not be very different, the Boer ranks include many below as well as above the age limits which obtain in the British army. I have seen a boy of 11 years of age brought by his father on commando from the Free State. There were many under 16 and 17 years of age, and many over 40 years of age. Men suffering from organic disease, such as of the heart, which would unfit them for any unusual fatigue went on commando. The Boers who were commandeered in the district in which I lived were not subjected to any medical examination to prove their fitness for service, and in one case I gave a certificate of unfitness for service to a man with phthisis partially arrested but still with extensive signs in one lung, but the certificate was disregarded by the officials and the man was sent to the front, where he took part in a reconnaissance which took up 22 hours and completely knocked him up. A few days later the man obtained another certificate from a Free State surgeon, for which he paid a guinea, and was then allowed to return home.

OVERWORKED TOMMIES.

There can be little doubt that the cause of the disaster at Stormberg was bad generalship. The men were tired out before the fight began. During the retreat, after the battle, many of the men are said to have dropped down and fallen asleep from sheer fatigue. It is said that many who were taken prisoners there were found lying fast asleep in their trenches. The prisoners told us that they had marched all the night before the battle and had had very little sleep during the preceding night. Notwithstanding this, and the fact that all the advantages of position were with the enemy, some of the Boers themselves admitted that our men had made a good fight. Had it not been for the loss of their leaders at a critical moment through the mistake of our own artillery, many think that the result of the battle would have been very different. Of course, on special occasions men must have severe strain put on their powers of endurance, but there is a limit, and from all I have heard this limit was much exceeded in the operations ending in the battle of Stormberg. Further, I have heard that it was the practice of the officer commanding a regiment recently stationed in this neighbourhood very frequently in the mornings to take the men a long march to the top of some stiff hill before breakfast, bringing them back so fatigued that when breakfast time arrived many of them had no appetite for it. This sort of thing would be well enough once in a way, but to make a frequent practice of over-fatiguing the men before they have had any food would hardly improve their fitness for service.

SANITARY ARRANGEMENTS—BOER AND ENGLISH.

The absence of proper sanitary regulations in the Boer laager at Stormberg was a disgrace to any nation that pretended to civilisation. Dead animals and the remains of slaughtered sheep and oxen lying about unburied caused a terrible stench. In the offices and waiting-rooms at the railway stations all sorts of refuse were allowed to accumulate, and in some instances dead horses were left behind inside the railway offices. There was a good deal of sickness and at least two fatal cases of enteric fever occurred among the Boer forces at Stormberg. At the same time the sanitary arrangements for our troops who were stationed in, or who passed through, the district were not free from reproach. At the Bethulie Bridge camp the stench along the river bank and for some considerable distance from the river was bad. The same thing was noticeable at Sterkstroom camp. At Burghersdorp station at the time when large numbers of troops were passing through, according to the stationmaster on more than one morning the station yard was in a disgusting state. These things ought not to be. Proper sanitary arrangements for large bodies of troops in transit may be difficult to arrange, but surely some steps could be devised which would obviate such a state of affairs as that just mentioned. With reference to the camps there is less excuse; either the sanitary arrangements must have been at fault, or the discipline for their proper enforcement must have been lax. Many of the cases of typhoid fever which have occurred among our troops lately may have been unavoidable—for instance, in the case of the men surrounding Cronje's laager at Paardeberg—but other cases have probably occurred which might have been avoided by more attention to sanitary arrangements and stricter discipline in this matter. At Bethulie Bridge the water from the Orange river was used for drinking purposes. My opportunities for observations regarding military sanitary arrangements have been confined to this district. It is to be hoped that elsewhere matters were better regulated.

THE OBJECT OF THE WAR.

From the talk of the farmers and Free Staters there is no doubt that the object of this war was aggressive not defensive—to get rid of English authority and government from the whole of South Africa. At a Bond meeting held in this district about a year ago one speaker said that he prayed that the day might come when the whole of Africanderdom would be free from the foreign yoke. No one made any protest against this statement. One of the Free State commandants addressing a number of recruits on the market square of Burghersdorp last November said, "We have come to assist you in throwing off the foreign yoke." Very little was heard of saving the independence of the Republics, but the common talk among the farmers was of "cleaning the land" or "driving the British into the sea." The Dutch farmers were urged to join in a triumphal progress through the colony, in which no serious opposition was expected from any British troops. They were told by Free Staters that it would be only a matter of a few weeks and that in

every district which they reached they would be joined by large numbers of Africanders, and they talked of drinking champagne in Cape Town over their conquest within a month. With the great majority of the burghers their confidence of success was absolute. One burgher said that after they had killed all the English soldiers General Joubert would hire a ship and they would send him and his men to England to fetch "Victoria" out of her house and bring her to the jail at Pretoria.

BOER NEWS—OFFICIAL AND OTHERWISE.

An information commission at Bloemfontein sent out official telegrams recording the progress of the war. On the whole the news was reliable, but in one point these official telegrams consistently perverted the truth. They grossly exaggerated the casualties on the British and always understated those on the Republican side. For instance, after Belmont the official telegram stated the Boer losses as ten killed and 40 wounded, and said that the British losses were estimated at far in excess of 2000. In this instance they seem to have divided their actual losses in killed by ten whereas they multiplied ours by about the same figure. Current gossip exaggerated the British casualties still further. We were said to have lost 7000 or more men at Belmont. At Magersfontein we were reported to have lost 9000 killed, and the blood had run four feet deep. The man who brought this report said that he had it from the lips of a minister of the Dutch Church so that it must be true. Our losses were heavy but when they were exaggerated to this extent it is not to be wondered at that the Dutch farmers imagined that there was little chance of British success in this war. When the news of the naval brigade fighting under Methuen reached them it was said that England evidently had no more soldiers to send and was sending sailors to fight now.

CONCLUSION.

In justice to the Free State officials it is only fair to state that in Burghersdorp the English residents were on the whole very fairly treated. Among the Free State burghers drunkenness was certainly less in evidence than with our own men. The liquor regulations during the Boer occupation were more stringent. As soon as the town was re-occupied the difference in this respect was painfully brought to our notice.

TACHYCARDIA FOLLOWING ENTERIC FEVER.

BY CHARLES BURLAND, M.D. BRUX., F.R.G.S.,

LATE PRESIDENT OF THE BRUSSELS GRADUATES' ASSOCIATION, PRINCIPAL MEDICAL OFFICER TO H.M. HOSPITAL TRANSPORT, NO. 77.

THE subjoined synopsis of cases of enteric fever and dysentery which recently came under my care as medical officer in charge of one of the hospital transports from South Africa to Southampton, and the preponderance of typhoid fever cases will, I trust, plead my excuse for submitting a somewhat extensive and varied personal experience to the readers of THE LANCET.

There were under my care, out of a total of 632 patients, 265 cases of enteric fever and 82 cases of dysentery. All these patients had been discharged direct from hospital to the steamer in the early stages of convalescence, and one pronounced symptom which was present in the majority of cases greatly impressed me; this was an unusually rapid, small, and compressible pulse peculiar to the enteric fever cases, associated with signs of early cardiac dilatation. For purposes of investigation I enlisted the help of Surgeon-Captain Fenwick of the New Zealand Mounted Infantry and we made a careful and exhaustive examination of 300 cases of enteric and dysenteric convalescents. In every case in which the pulse-rate exceeded 90 the heart was examined binaurally by Surgeon-Captain Fenwick and myself.

Roughly gauging the severity of the illness by the past military history, as regards work and hardships; having regard, in the case of civilian soldiers, to the sufferer's previous occupation and habitual mode of life; calculating the number of weeks which were spent in hospital; and after prolonged and searching individual examination we obtained the following results. The lowest pulse-rate in the military enteric fever cases was 72 per minute and the highest was 150, an average exactly of 98·25. In 56 per cent. the pulse-rate was 80; in 25 per cent. it was 95; in 10 per cent. it was 100; in 5 per cent. it was 110; and in 4 per cent. it was from 120 to 140.

In investigating 50 cases of dysentery we found an average pulse-rate which varied from 72 to 80. The number of hearts examined was 75 per cent. of the total cases. In five cases valvular disease was present and these were excluded. In 25 per cent. of those examined the apex beat was displaced. In 50 per cent. the impulse was diffused, undulatory, and difficult to localise. A feeble first sound and a sharp and accentuated second sound were frequent features, while in a small percentage of cases undoubted dilatation was present.

The following is an interesting case illustrating the points which I wish to bring forward.

A Scots Guardsman, aged 30 years, a man of superb physique, came on board apparently convalescent. Seven days later he collapsed suddenly on deck and was at once placed in his cot. His condition was so serious that I summoned Dr. Atherstone, assistant medical officer, in early consultation. The pulse at this time was 150, and was thin and compressible. Dyspnœa was distressing, the face was pinched, cold, and markedly blanched, while the body was covered with a clammy sweat. The patient complained of acute abdominal pain and the abdomen was tympanitic but not rigid. The pain on deep-seated epigastric pressure was excruciating. I was inclined to regard the case as one of acute cardiac failure, but as there seemed to be a possibility of perforation—these men take every opportunity of eating forbidden food surreptitiously—I asked Surgeon-Captain Fenwick for the benefit of his surgical experience. It was decided to continue the medical treatment. The patient rallied slightly under a very free exhibition of stimulants, but expired 36 hours after his first seizure.

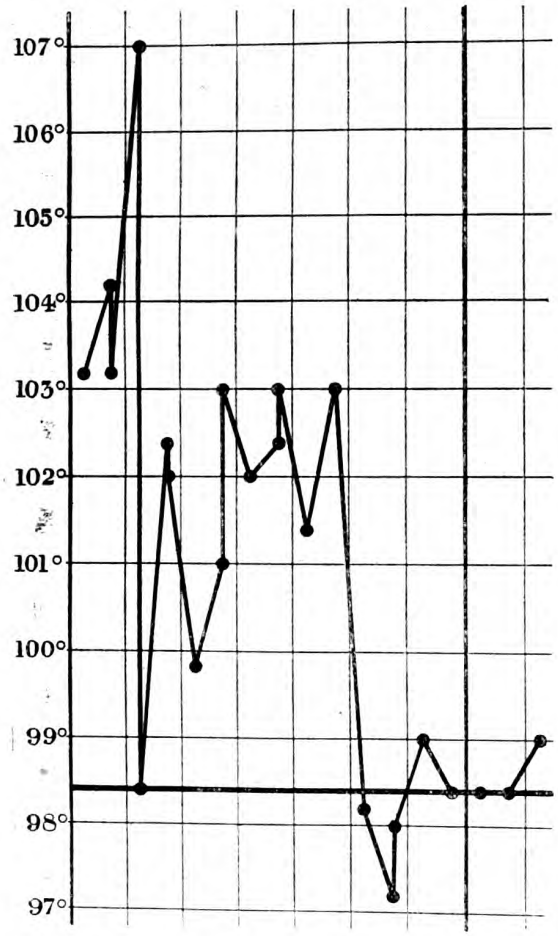
The post-mortem examination, one hour after death, revealed enlargement of the heart with dilatation of the left ventricle. The valves were healthy; the lungs were deeply congested; the abdomen was healthy; there was no perforation; and the cardiac walls, left ventricle especially, were very thin. The finger readily perforated the heart substance on slight pressure.

My experience of typhoid fever had hitherto, I confess, led me to coincide with the views of the recognised English and American authorities on the slow pulse usually found in convalescent patients from this disease, and it was certainly startling to find that of all my convalescents not 2 per cent. had a pulse-rate below 70.

How can this rapid pulse-rate in military patients be accounted for? Surgeon-Captain Fenwick adduced a theory of sympathetic irritation which I could not bring myself to accept, but which nevertheless recalled cases of physical exhaustion and cardiac disturbance with rapid, feeble pulse due to hardship and privation, which I, in common with other travellers, have found associated with mountain sickness upon the Himalayas, similarly with well-known phenomena which occasionally prevail in the collapse attending persistent and aggravated sea-sickness. It must, of course, be remembered that in the enteric fever cases which I now portray the majority of the patients had been grievously debilitated by fatiguing marches and poor and irregular feeding—thus engendering a state of cardiac irritation which the subsequent typhoid fever had not conduced to allay. May we not assume that the symptoms described are the natural and inevitable sequelæ of such conditions?

I have selected the following cases of relapsing enteric fever and dysentery, my object being to show that although the dysenteric attacks equalled the enteric in severity, yet in the former disease the pulse-rate was markedly slower.

CASE 1.—An officer, aged 27 years, who went through the whole siege of Kimberley, where he distinguished himself by his unceasing energy, had an attack of typhoid fever and was in due course invalided home. Surgeon-Captain Fenwick, who knew him intimately, stated that he was apparently quite convalescent when discharged from Wynberg Hospital. The patient complained of feeling ill directly he reached the ship and was admitted to hospital treatment at once. After a trying illness, which presented all the features of a severe primary attack but which were unquestionably due to a terribly bad relapse, he suddenly had an attack of cardiac failure on the fifth day of the homeward voyage. He was extremely ill throughout the remainder of the journey



and was eventually despatched by ambulance to Netley Hospital on the arrival of the ship in England.

CASE 2.—A soldier, aged 30 years, had a very severe relapse two days after embarkation. He was much emaciated and was for several days in grave danger. The heart was weak, but the pulse, after the initial rise, was uniformly steady and slow. It will be seen to what a high degree his temperature rose (107° F.).

CASE 3.—A ship's fireman, one of the crew of the transport, had a severe attack of typhoid fever. The pulse was steady and slow and the heart's action was forcible and good.

Case 2 and Case 3 would seem to contradict completely my statements regarding the rapid pulses of my soldier patients, but as a matter of fact the patient in Case 2 had been on garrison duty, with no marching or hardships, while the patient in Case 3 was a ship's fireman with regular hours of duty.

I make no comment on the cases, my only object being

This chart serves to illustrate the severity of some attacks of dysentery. Many writers state that a temperature above 102° F. is unusual, but I have not unfrequently seen the temperature in this disease rise to 104° and over. In this particular case I had a doubt as to the existence of hepatic abscess, but the patient's rapid recovery dispelled this idea.

to show that although the relapses were equally severe, yet a marked difference was noticeable in the cardiac action in the two diseases.

The treatment was simple, consisting of free stimulation with brandy and champagne, while digitalis, carbonate of ammonia, and strychnia were the drugs chiefly relied upon, the latter being administered hypodermically in several extreme cases.

Among the enteric fever cases were four who had undergone antityphoid inoculation. My experience of these does not justify me in saying more than that they appeared to have been mild attacks with an early and uninterrupted convalescence. With regard to the treatment of dysenteric cases I found that doses of ipecacuanha administered by the mouth in the manner I advocated some years ago in your columns,[1] in an article on hæmatemesis, were most effectual, the one point being to soothe the stomach by a small dose of opium, a short time before administering a bolus of ipecacuanha (20 grains) moistened with a few drops of glycerine, all liquids being absolutely prohibited for some hours after the medicine. Cases in which the drug was rejected when given by the mouth were treated by rectal injection.

While regretting that the military exigencies and the ever-increasing demand for hospital accommodation should necessitate such early removal of patients before they are really fit to travel—to which must be in a measure attributed the very serious relapses which have occurred—it must be remembered that as the Equator is approached meteorological and climatic conditions are encountered which are sufficiently trying even to persons in health.

Infinite credit is due to the Royal Army Medical Corps for their unceasing devotion to their patients, and it is in no spirit of criticism upon them that I record these observations.

To Colonel J. F. Supple, R.A.M.C., principal medical officer, Lieutenant-Colonel O'Connor, R.A.M.C., and Major Tatham, I tender my humble tribute of admiration for the excellent arrangements which they made for the embarkation of patients, combining a minimum of fatigue with a maximum of comfort. To these gentlemen, also, we were indebted for our well-organised hospital and excellent staff.

To Captain Sir E. Chichester, Bart., R.N., we all owed much; no suggestion for the benefit of the sick and wounded failed to secure his kind and patient attention and practical coöperation.

In conclusion, I trust that the officers of the Royal Army Medical Corps, whose experience of typhoid fever cases has of late been enormous, will give the profession the benefit of their observation, especially with regard to the points which I have raised.

A FURTHER NOTE ON
THE INFLUENCE OF THE TEMPERATURE OF LIQUID HYDROGEN ON BACTERIA.[2]

BY ALLAN MACFADYEN, M.D. EDIN.,
AND
SYDNEY ROWLAND, M.A.

IN previous communications we have shown that the temperature of liquid air has no appreciable effect upon the vitality of micro-organisms, even when they are exposed to this temperature for one week (about – 190° C.)[3] We have now been able to execute preliminary experiments projected in our last paper as to the effect of a temperature as low as that of liquid hydrogen on bacterial life. As the approximate temperature of the air may be taken as 300° absolute, liquid air as 80° absolute, and hydrogen as 21° absolute, the ratio of these temperatures roughly is respectively as 15 : 4 : 1. In other words, then, the temperature of liquid hydrogen is about one-quarter that of liquid air, just as that of liquid air is about one-quarter of that of the average mean temperature. In subjecting bacteria, therefore, to the temperature of liquid hydrogen we place them under conditions which, in severity of temperature, are as far removed from those of liquid air as are those of liquid air from the condition of the average summer temperature. By the kindness of Professor Dewar the specimens of bacteria were cooled in liquid hydrogen at the Royal Institution. The following organisms were employed: bacillus acidi lactici, bacillus typhosus, bacillus diphtheriæ, proteus vulgaris, bacillus anthracis, bacillus coli communis,

[1] THE LANCET, Oct. 14th, 1893, p. 923.
[2] A paper read before the Royal Society on May 31st, 1900. Communicated by Lord Lister, P.R.S.
[3] Proceedings of the Royal Society, Feb. 1st and April 5th, 1900. THE LANCET, March 24th (p. 849) and April 21st (p. 1130), 1900.

staphylococcus pyogenes aureus, spirillum choleræ, bacillus phosphorescens, bacillus pyocyaneus, a sarcina, and a yeast.

The above organisms in broth culture were sealed in thin glass tubes and introduced directly into liquid hydrogen contained in a vacuum jacketed vessel immersed in liquid air. Under these conditions they were exposed to a temperature of about – 252° C. (21° absolute) for ten hours. At the end of the experiment the tubes were opened and the contents were examined microscopically and by culture. The results were entirely negative as regards any alteration in appearance or in vigour of growth of the micro-organisms. It would appear, therefore, that an exposure of ten hours to a temperature of about – 252° C. has no appreciable effect on the vitality of micro-organisms.

We hope to extend these observations upon the influence of the temperature of liquid hydrogen on vital phenomena and to make them the subject of a future communication, and to discuss their bearing upon problems of vitality.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ACTINOMYCOSIS.

BY EDWARD T. JONES, M.R.C.S. ENG.,
AND
JOHN C. MACKAY, M.D. ST. AND.

THIS case appears to be worth recording because of (1) the uncommonness of the disease and (2) the enormous doses of iodide of potassium taken during treatment. The patient was a male, aged 42 years, who is the driver of a traction-engine used with a threshing-machine. Early in November, 1898, he had an old stump of a tooth removed from the right side of the lower jaw. This was followed by enormous swelling of the tongue accompanied by great pain. This apparently subsided under treatment and he came under our care a month later with a large swelling under the jaw in the anterior triangle, which was rapidly increasing. The skin was very red, thickened, and œdematous; the tongue was bound down and when protruded came out markedly on the right side. At one spot there was a patch of softening, this was incised and was found to contain thick curdy pus loaded with actinomycotic granules (confirmed by the Clinical Research Association). The treatment adopted was to open all places of softening as they appeared, to swab out the cavities with 1 in 3 carbolic solution, and to administer iodide of potassium internally. The dose of the iodide was increased from 30 grains per day to a maximum of four drachms per day in the course of six weeks. The patient never had any unpleasant symptoms from the iodide; in fact he put on flesh. The changes in the discharge and granules due to the iodide as recorded by Fairweather[1] were observed. The disease proved extremely chronic, spreading in the subcutaneous tissue downwards and forwards over the larynx, crossing the middle line. Finally it cleared up and early in March, 1899, the patient was discharged with no further sign of the disease and with nearly all the induration and thickness of the skin gone. Whether the iodide had much to do with the apparent cure it is difficult to say. Indications for treeatment were not easy to find. Veterinary surgeons appear to treat their cases in cattle with enormous doses of iodide with success. Perhaps more radical surgical treatment at the beginning, as recommended by Ransome,[2] would have produced a good result more quickly, but on the other hand it is worth noting that with the exception of one week at the commencement of treatment our patient was able to keep at his work during the whole time.

NOTE ON THROMBOSIS OF CEREBRAL VEINS OCCURRING IN A CASE OF CHLOROSIS.

BY EDWARD F. M. NEAVE, M.B., CH.B. EDIN.

THROMBOSIS of cerebral veins or sinuses is a very rare complication of chlorosis. Dr. Byrom Bramwell in his book on anæmia states that "thrombosis of the veins of the leg occasionally occurs [in chlorosis], but thrombosis of the cerebral sinuses very rarely." He does not record a single case of the latter. I have not been able to ascertain the frequency of this complication, but judging from the scantiness of the literature on the subject it must certainly be very rare. On consulting Osler's "Practice of Medicine" I find that Brayton Ball has recently reported a case and has collected 10 or 11 others from the literature of the subject. All were in girls with anæmia or chlorosis. Ball's patient was dull and stupid and had vomiting, dilatation of pupils, and double-choked discs. Slight paresis of the left side occurred. In some of the other cases the patients had headache, vomiting, and delirium. In Douglas Powell's case with similar symptoms there was loss of power on the left side.

The diagnosis of cerebral thrombosis is very difficult and in many of the cases it was made only at the necropsy. The symptoms pointing to thrombosis in the cerebral sinuses and veins are described by Sir Dyce Duckworth[1] as follows: "(1) headache, at times very severe, and sometimes plainly localised; (2) vomiting, generally severe; (3) motor symptoms, indicative generally of irritation, either cortical or central—hence tremors, jerking, spasms, and contractures in other parts, usually of one side, ending in paresis or paralysis; (4) drowsiness, delirium, coma; (5) variations in the size of the pupils."

The following case, in which most of the above symptoms were present, seems worthy of record:—

The patient was a married woman, aged 31 years, and she had no children. She complained of breathlessness, palpitation, and weakness. The duration of the illness was indefinite, but she had felt ill for some months and ultimately became so weak that she had to take to her bed. The family history was good. The patient had anæmia when a girl several times, but she always quickly recovered under a course of iron. When I visited her on May 19th, 1900, I found her lying in bed on her back, looking extremely exhausted and presenting most of the typical features of chlorosis. Her development and nutrition were good, but her face was extremely blanched and the lips and conjunctivæ were very pale. Pulsation was visible in the neck and a *bruit de diable* was well marked. On the 20th the patient had a few fainting fits, from which she always quickly recovered. On the next day (the 21st) she had a severe attack of vomiting, with severe headache. A blue pill, followed by a saline draught, was given with some benefit. On the evening of the 22nd she seemed very weak and could not turn on to her side. She slept fairly well but on awakening next morning she complained of a feeling of numbness in the left arm and leg, saying that those members appeared to be "dead." At the time she complained of great pain over the vertex and frontal region. This pain could not be localised to any one side. Her memory was confused—for instance, she did not know the day of the week or what she had had for breakfast. She was slightly delirious at times. The speech was unaffected. There was paralysis of the left arm and leg. As regards the leg the paralysis was complete, while the paralysis of the arm was partial. The opponens and adductor of the thumb were in action, the flexors of the wrist were slightly in action, while all the other muscles of the limb were paralysed. There was no facial paralysis. When the tongue was protruded it pointed distinctly to the right side. The left knee-jerk was slightly exaggerated. There was no ankle clonus. At this time there was incontinence of urine. The pupils were very large and they reacted to both light and accommodation. The discs, beyond being pale, seemed normal. There was no optic neuritis. The urine contained no albumin or sugar. The pulse was 120 and the temperature was 100° F. As regards the sensory symptoms there was slight anæsthesia of the left arm and leg. There was no hyperæsthesia.

[1] THE LANCET, Feb. 22nd, 1890, p. 404.

Dr. J. Russell of Arbroath saw the patient with me and after weighing carefully all the possibilities we came to the conclusion that the cause of the hemiplegia was a clot of blood in one or other of the cerebral sinuses or veins in the region of the right motor area. We excluded secondary thrombosis, i.e., thrombosis due to disease of the internal ear, fracture, tumour, or suppurative disease. Embolism was excluded.

Under appropriate treatment the patient gradually improved. A belladonna plaster was applied over the præcordial region, while digitalis, nux vomica, and iron were given internally. The bowels were kept regular with cascara. A light nutritious diet was added. In two days under this treatment improvement was noted. The temperature and pulse gradually came down to the normal, and six days later the paralysis of the arm began to pass off. The patient could not move her toes till about three weeks from the time that the paralysis occurred, and three weeks later she was up and limping about. Two months after the beginning of her illness she was practically quite well, except for some dragging of the left leg.

Friockheim, N.B.

A CASE OF ABSCESS OF THE PAROTID GLAND PRESENTING UNUSUAL SYMPTOMS.

BY W. J. BEVERIDGE, L.R.C.P., L.R.C.S. IREL.,
SURGEON TO THE CAYLLOMA SILVER MINING COMPANY, LIMITED.

ON May 14th of this year I was consulted about an Indian boy, aged about 10 years, who was suffering from an inflammatory swelling involving the right side of the head and face. He gave the following history. He had had a slight soreness in the throat, accompanied by pain over the right parotid region from May 2nd. On the 6th he noticed a swelling in front of the right ear. This swelling increased during the following days, spreading forwards over the cheek and upwards over the temporal region; from the temporal region it spread backwards and downwards, till on the 11th he noticed (to use his own expression) "a soft pimple" in the groove behind the helix of the ear. The boy presented a most peculiar appearance. The helix of the ear was tilted forward by an abscess situated in the groove behind; the position of the zygoma was marked by a hard groove, below which there were œdema and deep fluctuation; and there was considerable œdema over the temporal region and extending down to the mastoid process. Both tonsils were slightly swollen. The pus sac behind the ear being evidently about to burst I opened it, allowing a quantity of pus to escape. The flow of pus was greatly increased by pressure over the parotid. I applied an absorbent dressing and gave the boy a boric acid gargle. On the next morning I made an incision into the parotid, opening into a fairly large abscess into which I inserted a gauze drain. A considerable quantity of purulent matter escaped during the next few days. The œdema rapidly diminished and the boy is now quite well. I have no doubt that the lesion in this case was the very ordinary abscess in the parotid region following on the introduction of septic organisms through the tonsils. In this case, however, the pus worked its way upwards, passed under the zygomatic arch, then backwards beneath the strong temporal fascia, escaping under the lower border of which it was at length able to reach the surface. Previously to my seeing the patient no treatment whatever had been applied.

AUGUST BANK HOLIDAY ON THE CONTINENT.—For the convenience of holiday-makers on the Continent cheap tickets will be issued to Brussels available for eight days, viâ Harwich and Antwerp. Passengers leaving London in the evening reach Brussels next morning. Tickets at cheap fares will be issued by the Antwerp route to Berne from July 25th to 28th. For visiting The Hague, Amsterdam, and other parts of Holland, the Rhine, north and south Germany, and Bâle for Switzerland, especial facilities are offered viâ the Great Eastern Railway Company's Royal British Mail Harwich—Hook of Holland route, through carriages being run to Amsterdam, Berlin, Cologne, and Bâle, also restaurant car on the North and South German express trains to and from the Hook of Holland. The General Steam Navigation Company's fast steamers will leave Harwich for Hamburg on August 1st and 4th, returning August 5th and 8th.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

BELGRAVE HOSPITAL FOR CHILDREN.

A CASE OF CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.

(Under the care of Dr. EDMUND CAUTLEY.)

CONGENITAL hypertrophic stenosis of the pylorus is still sufficiently uncommon in this and other countries to warrant placing the following instance of the disease on record. It is a remarkable circumstance that as soon as a new morbid condition is described many older records of its occurrence are discovered, and before long it is found to be by no means so rare as was thought at first. Dr. Cautley's paper on hypertrophic stenosis of the pylorus in infants, read before the Royal Medical and Chirurgical Society in November, 1898, though not the first account of this interesting disease, contained the first thorough description of the condition with a collection of the previously recorded cases. We have no certain knowledge of the real cause of this malady, and so far the only satisfactory treatment appears to be surgical.

A female infant, aged three months, was admitted into the Belgrave Hospital for Children under the care of Dr. Edmund Cautley on June 29th, 1900, and died on the next day. Her parents were described as healthy. She was born at full time and seemed to be a normal infant. She was the fourth child, the others being alive and well. The mother had had no miscarriages. During the first six weeks of life the infant was fed on cow's milk and barley-water, and was said to have had about a pint of the former in the 24 hours. She was constantly sick and was then put on one teaspoonful of condensed milk with four tablespoonfuls of water and lime water for a feed, and was only fed four times a day. During the two days before admission she had meat juice and whey. The mother's account of the feeding and of the past history generally was variable and unreliable. She stated that the vomiting had been constant since birth, the food being kept down only a short time, and that constipation had been very troublesome. For three weeks before admission the vomiting and wasting had been more pronounced.

On admission the child was dirty, flea-bitten, and emaciated, weighing 6 lb. 3 oz., and had occasional slight general convulsive movements. The temperature was normal. The vomiting was frequent and persistent, food being retained a very short time. There was no bile in the vomited matter. The bowels acted five times; the stools being small, watery, and greenish, and containing traces of fæcal matter. The convulsive movements became continuous and the temperature gradually rose, reaching 105° F. before death, which took place a few hours after Dr. Cautley first saw the child.

Necropsy.—On making a post-mortem examination it was found that there was great emaciation. The stomach was largely dilated and its walls were thinned, except in the region of the pylorus where the wall was thicker than usual in these cases. The contents consisted of a little partially digested food and some excess of mucus. The mucous membrane was not inflamed but presented a slightly catarrhal appearance. The pylorus formed a definite elongated, cylindrical tumour which was an inch long and firm and hard. Its limits were very easily defined, especially on the duodenal side. On laying open the duodenum the pylorus presented the same appearance as the os uteri when seen from the vagina—a small central orifice surrounded by a thick, smooth, ring-like wall. Occlusion of the orifice was completed by the folds of mucous membrane, and the liquid contents of the stomach could not be squeezed through it, though a small probe could be passed through into the stomach. On laying open the pylorus longitudinally it was noted that the mucous membrane was

thrown into a thick, raised, ridge-like fold, bifurcating into the mucous membrane of the stomach. The wall was three-eighths of an inch thick at the duodenal end and thinned off towards the gastric end, though very definitely limited in this direction, hence the pylorus as a whole was somewhat funnel-shaped. As in previous cases the increase in the thickness of the wall was due to hypertrophy of the circular muscular fibres. The intestines were collapsed and empty. The other organs were normal.

Remarks by Dr. CAUTLEY.—In a paper[1] on this affection read before the Royal Medical and Chirurgical Society in 1898 I described two typical cases of this disease which came under my care in 1897; mentioned a specimen in the St. Bartholomew's Hospital Museum presented by Dr. J. Raglan Thomas and subsequently shown at a meeting of the Pathological Society of London by Dr. H. Morley Fletcher;[2] and gave brief abstracts of 17 other typical cases collected from medical literature, and also short notes of six allied cases which were not sufficiently definite to be included as typical. Since that paper was written no less than 11 other instances have been recorded by Schwyzer,[3] Stern,[4] Rolleston and Hayne,[5] Meltzer,[6] Adler (referred to by Meltzer),[7] Abel,[8] Still[9] (three cases), Batten,[10] and Pritchard.[11] Together with the present case this makes a total number of 32 undoubted cases. It is noteworthy that no less than 26 of these have been recorded in the last five years. It is clear, therefore, that the disease is not so rare as has been supposed.

Fuller details of the symptoms, diagnosis, pathology, and morbid anatomy of this condition will be found in the paper first referred to. In only one respect does the present case differ from the typical instances—namely, in the small, watery stools passed during the last day of life. Complete constipation is the condition usually present. It was noted at the necropsy that the intestines were practically empty and that the occlusion of the pylorus was complete. Possibly the stenosis is aggravated by post-mortem contraction of the hypertrophied muscle and during life it is not quite so extreme.

The two chief theories put forward as to the causation of the disease are as follows:—1. It is due to a simple redundancy of fœtal growth. Nature, in her extreme anxiety to provide an efficient pyloric sphincter, has over-exerted herself and produced too great a quantity of muscular tissue. 2. Thomson[12] suggests that the essential lesion is not a muscular but a nervous one—a functional disorder of the nerves of the stomach and pylorus leading to ill-coördinated and therefore antagonistic action of their muscular development. Neither of these theories is completely satisfactory and the affection still requires further elucidation. Treatment consists in giving small, easily digested, or pre-digested meals. Nasal feeding has proved beneficial. Rectal feeding prolongs life. Probably the only chance of permanent benefit lies in operation. In Abel's case operation resulted in cure; that is to say, the child was discharged from the hospital as cured in two weeks. So far no other successful operation has been recorded. Pylorectomy offers the best chance of success. It is, no doubt, a serious operation and, apart from that, the infant when the disease is diagnosed is hardly in a condition to stand such an operation. Now that more attention has been attracted to the subject it is probable that an earlier diagnosis will be made and more successful results will be attained.

NEWCASTLE-ON-TYNE ROYAL INFIRMARY.

A CASE OF HYDATID OF THE LIVER AND SUPPURATING HYDATID OF THE LEFT LUNG.

(Under the care of Mr. RUTHERFORD MORISON.)

THE early diagnosis of the presence of an hydatid cyst in the lung is very difficult, and though exploratory puncture may afford definite information in doubtful cases, yet the danger of rupturing the cyst during the puncturing and of flooding the lungs with the hydatid fluid is by no means small, several fatal cases having been recorded. When the hydatid has given rise to an empyema the treatment is much more simple. The modern method of treating hydatids of the liver by incision after free exposure of the organ gives much more satisfactory results than those obtained by tapping, as it is possible to remove every portion of the parasite and the cavity in the liver is gradually obliterated. For the notes of the case we are indebted to Dr. Henry Fielden, house surgeon.

The patient was a single woman, aged 30 years, who was admitted into the Royal Infirmary, Newcastle-on-Tyne, on March 3rd, 1899, complaining of a swelling on the right side. She stated that in August, 1895, she began to suffer from pain below the right breast and at the top of the right shoulder, increased by deep breathing and by swallowing. The pain on swallowing was so prominent a symptom that her condition was attributed to indigestion. At Christmas of the same year she noticed that the right side was becoming larger and at the same time the pain was more marked than it had been before. She continued going about her housework suffering in this way till August, 1898, when she had a severe attack of pleuritic pain in the left side which was accompanied by a dry cough. For this attack she remained in bed for three days and then got up. She had only been up for three days when while walking along a landing she was seized with a violent, continuous fit of coughing which lasted from 7.30 P.M. to 4.30 A.M. and almost a gallon of muco-purulent material was expectorated. To her medical attendant the case now assumed all the appearances of phthisis and this it was considered to be. This appearance was rendered still more deceptive by the occurrence 12 months previously of hæmoptysis. Until she reached the age of 15 years her parents had a dog living in the house. From the age of 18 years she was maid in a hotel where she was accustomed to eat freely of green vegetables. On admission she had the appearance of a patient suffering from phthisis. She had a cough and expectorated a good deal of muco-purulent material. Respiratory movements were much freer on the right than on the left side, especially at the base, and the base of the right chest bulged. Percussion gave a resonant note all over the chest except over an area of about the size of the palm of the hand below the scapula on the left side, where there was a great loss of resonance but not absolute dulness. The breath sounds were rather harsh on the right side. At the left base behind the breath sounds were feeble and were accompanied by bubbling râles. The heart sounds were normal. There was a large swelling in the right hypochondrium which made the ribs bulge forward and moved with respiration. The swelling felt elastic and fairly tense. On percussion it was possible to obtain a "hydatid thrill." The liver dulness was increased. A diagnosis of hydatid of the liver was made.

An operation was performed on March 9th. Under chloroform a transverse incision was made from the right rectus in front to the quadratus lumborum behind and the liver was freely exposed. An exploring syringe was then introduced into the liver and a clear fluid like hydatid contents was drawn off. The liver was then incised, the cyst was opened, and the contents of the cyst, about half a gallon of fluid and daughter cysts, escaped. By the aid of lithotomy forceps, sponges, and washing the whole of the remainder of the cyst wall was removed. No pus was discovered. A gauze drain and a tube were then introduced into the cavity and the abdominal wound was closed except behind where the tube and gauze were left projecting into the loin. For some time the temperature remained elevated and the cough was extremely troublesome. On the 25th she expectorated some muco-purulent material containing "grape skins." The base of the left chest was examined and was found to present the physical signs of an empyema. An exploring needle was inserted on the 29th and pus was drawn off. On the same day chloroform was administered and portions of the seventh and eighth ribs were removed, and the collection of pus in the lung was cut into, when a large number of cysts escaped. A gauze drain and tube were inserted and she had no further bad symptoms. The cough almost entirely ceased. She was discharged on May 4th; she had regained perfect health and is now in a housemaid's situation.

Medical Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Untoward Results following Abdominal and Pelvic Surgery and the Means to Prevent them.

A MEETING of this society was held on July 13th at Buxton, Dr. W. J. SMYLY (the President) being in the chair, a number of the Fellows of the society and their lady friends being previously hospitably entertained. The scientific work of the meeting took place in the Town Hall, where Mr. J. E. HARRISON, vice-chairman of the Buxton Urban District Council, delivered an address of welcome, which was acknowledged by the PRESIDENT.

Mr. CHRISTOPHER MARTIN (Birmingham) showed a specimen of Ruptured Cornual Pregnancy.

Mr. CHARLES RYALL showed a specimen of Necrosis of the Cervical Stump following Supra-Vaginal Hysterectomy.

Mr. E. STANMORE BISHOP (Manchester) introduced a discussion on Untoward Results following Abdominal and Pelvic Surgery, and the Means to Prevent them. He said that defective results after abdominal or pelvic work reacted upon future cases to the detriment of the reputation of the operation itself, and deterred other patients from resorting to operation in time to receive effective treatment. The type of operation which Mr. Bishop selected for discussion was that of hysterectomy for fibro-myoma. The defective results treated of were as follows: 1. Fatality, which was due most often to delay and next to sepsis. In connexion with this Mr. Bishop spoke of the advisability of early purgation and gave reasons for this and explained the rationale of its action and the methods of operation. 2. Ventral hernia; the percentage of occurrence was given and explanations offered for its occurrence, with the reasons for adopting suture in layers and the use of celloidin. 3. Intestinal and omental adhesions, which showed the need for perfect re-formation of the peritoneal potential cavity. 4. Vaginal prolapse; reasons were given for the closure of the pelvic peritoneum and the dangers of non-closure were pointed out. 5. Persistent sinuses, in connexion with which Mr. Bishop explained the preparation of the ligatures and the use of the drainage-tube. 6. Other defective results.

Dr. HEYWOOD SMITH remarked that he thought that subperitoneal hysterectomy was safer than panhysterectomy. The risk of ventral hernia could be minimised by making the incision not through the linea alba but an inch to one or the other side.

Mr. CHRISTOPHER MARTIN (Birmingham), in contrasting the various methods of hysterectomy, said that he failed to see what good the cervix could do after the rest of the uterus had been removed. The objection that the removal of the cervix weakened the vaginal vault and predisposed to prolapse was, he believed, a purely theoretical one. He had never seen such a result after panhysterectomy. Referring to the question of ventral hernia he said that he was at one time much opposed to the use of buried sutures, but since adopting the late Mr. Greig Smith's suggestion of boiling chromicised catgut in xylol or absolute alcohol he had not had any stitch abscesses and he thought that the plan of sewing up in three layers was the best.

Dr. MACNAUGHTON-JONES pointed out that the same rules hold good in gynæcological as in other branches of surgery, and he agreed with Mr. Bishop that cases requiring operation should be dealt with as soon as possible. He was quite satisfied with the three-layer method of sewing up; he never had any trouble with buried sutures and he had had only two cases of hernia following operation. The form of operation for hysterectomy that he preferred was the supra-vaginal.

Dr. E. T. DAVIES (Liverpool) said that in cases of fibroids where there were no symptoms it was very difficult to know whether to advise operation or not. He had had one case under observation for six or seven years and the patient had had no inconvenience from the tumour except from the æsthetic point of view. His preference was for Baer's operation, but he did not think that the stump of the cervix was of any importance in maintaining the vaginal vault, for no inconvenience was observed in cases where the uterus was completely removed by the vagina for cancer. Malignant degeneration of the stump appeared to him somewhat of a bugbear; he had read of the occurrence but had never seen a case.

Mr. CHARLES RYALL observed that hernia was due in some cases to the use of drainage through the abdominal wall and he had never adopted this plan without regretting it. The best way to drain was through the pouch of Douglas or by Muscatello's plan. Stitch abscesses were in some cases unavoidable when the intestine had been opened, for the fingers were then liable to become infected and, similarly, the abdominal wound might become infected with malignant disease if such a growth were allowed to come in contact with the abdominal wall during removal.

Dr. ROBERT BELL (Glasgow) considered that the danger of opening the abdomen was due entirely to sepsis; but it was only when the septic matter was in a condition for absorption that sepsis could occur. The view that sepsis could occur from bowel infection appeared to him to be entirely theoretical; if that view were correct why should not infection result from constipation? The number of cases of hernia following abdominal section was appalling—he was not speaking from his own experience for he had had only one case himself. To prevent it the first thing was to close the peritoneum carefully; the operator could then take proper time to secure the fascia and arrest all bleeding. By this means suppuration did not occur, and if healing took place by first intention there would be no subsequent hernia.

Mr. J. W. DRAPER (Huddersfield) said that in the cases of fibroid that had been under his observation in general practice (about 15) the patients had not been subjected to myomectomy. In one case the ovaries had been removed; in another, a case of small pedunculated fibroid producing pressure symptoms, the tumour had been removed. Of these patients none had died from the disease and most of them had passed the menopause. On the whole he believed that they had enjoyed a better life, in spite of the lumps which they carried about inside them, than they would have done if they had been operated upon; but these cases required watching.

The PRESIDENT said that his experience had been very different from that of the previous speaker. He had seen a large myoma forced down into the vagina and suppurating there; he had seen malignant degeneration, sloughing, and hæmorrhages threatening life as the result of not operating in cases of myoma. It was noticeable that in speaking of the risk of hernia everyone seemed best satisfied with the particular method of suture that he had last adopted; also most operators found herniæ in the practice of other men but not in their own. This was because, naturally, the patient did not come back to the man who had given her a hernia. His own plan was to be careful to secure the fascia, using boiled catgut. It did not seem to him that a strong case had been made out for celloidin. If a wound were aseptic it would heal whatever the dressing, and if it were not aseptic it seemed to him that celloidin would be a disadvantage.

Mr. STANMORE BISHOP briefly replied.

EDINBURGH OBSTETRICAL SOCIETY.

The Treatment of Dysmenorrhœa.—Election of Honorary Fellows.

THE special summer meeting of this society was held on July 11th, Dr. R. MILNE MURRAY, President, being in the chair.

Dr. F. W. N. HAULTAIN opened a discussion on The Treatment of Dysmenorrhœa. From a professional standpoint dysmenorrhœa might, he said, be defined as "pain associated with, and dependent on, menstruation of such severity as to materially interfere with the sufferer's performance of her usual duties." As a rule the pain was local and pelvic, but in certain cases it was referred to the head, the stomach, and to other organs. From the frequent presence of more or less discomfort along with menstruation the lay mind had come to consider pain as a physiological attribute of the function, and that even in an aggravated form the pain was to be borne with resignation, and that it was wrong, even if possible, to attempt amelioration. But pain at the menstrual periods sufficient to interfere with a woman's usual duties was to be considered pathological and was usually due to local abnormal conditions. Practically the causes of dysmenorrhœa might be briefly considered as inflammatory and obstructive, alone

or combined. The inflammatory variety embraced congestive and inflammatory conditions of any of the organs physiologically concerned in the function—the uterus and its appendages. The obstruction necessarily was confined to morbid states of the uterus alone. A rational explanation of the pain in the latter was that the blood which escaped from the capillaries of the uterine mucosa was impeded in its escape from the uterus. This might be by a temporary state of spasm or by a permanent blocking of the uterine canal through flexions, new growths, or developmental stenosis. The obstruction caused retention of blood which might or might not coagulate in the uterine cavity and which stimulated forcible contraction of the organ for its expulsion. When the pain was inflammatory it was due to the vascularity which occurred before menstruation still further congesting the already inflamed tissues; the discomfort was necessarily diminished after the depletion which occurred during the flow. The pain might be menstrual or pre-menstrual or both. The ovarian or tubal dysmenorrhœa was mainly pre-menstrual in its character, the depletion occurring as a result of the flow giving considerable relief. On the other hand, in uterine inflammation, such as endometritis, the pain, though pre-menstrual, might be continued through the period by the contractions of the tender uterus or by the thickened and swollen mucosa offering a block to the easy exit of the menstrual blood. Congested or inflamed ovaries gave rise to both menstrual and pre-menstrual pain. In Dr. Haultain's experience the obstructive or menstrual greatly preponderated over the other—in a proportion of quite ten to one. The treatment of dysmennorrhœa depended on the many different causes and it must be adapted to these causes. If a displacement were present it must be rectified; if a new growth, it must be removed; and if a stenosis, the dimensions of the canal of exit must be enlarged. By far the most common causes of this type were stenosis and flexions, the latter being usually a congenital anteflexion though exceptionally it was a retroflexion. In retro-displacements, replacement and retention in position was the only method to be adopted. In the most common congenital anteflexion with stenosis vaginal supports were practically valueless and uterine stems were dangerous to use, and therefore treatment in these cases consisted in dilatation or incision of the uterine canal to such an extent that mechanical obstruction was removed. Dilatation might be accomplished in two ways, forcibly or gradually. The use of the tent or the forcible dilatation by bougies up to 15 French or 10 Hegar was most efficacious, but in the majority of aggravated cases there was present a coincident endometritis, in which cases curettage with subsequent hot vaginal douching materially assisted in effecting a more rapid and permanent cure. Incision of the canal was not now so frequently adopted as formerly, but in well-marked cases of stenosis it was of much value in establishing a permanent dilatation of the cervical canal. Care should be taken to keep the incision open for 48 hours by packing with iodoform gauze. The treatment of the menstrual variety of dysmenorrhœa by means of drugs was most discouraging, a result to be expected if the cause was a mechanical obstruction. By drugs hope for alleviation of the symptoms only could be entertained. Unfortunately medicinal treatment consisted largely of the use of stimulants and anodynes, both of which were objectionable from their deleterious effect upon the general health and morale of the patient. Many dipsomaniacs and morphomaniacs could trace the origin of their degradation to the comfort given by alcohol and opium during painful menstruation. In inflammatory and congestive forms, particularly those due to ovarian causes, sedatives, such as bromides, gelsemium, camphor, and hydrastis, found most favour, combined with hot applications, hip baths, and counter-irritants. When the ovarian condition was intractable, it was in rare cases found necessary to perform oöphorectomy. This was very exceptional and was only applicable when for special reasons it was imperative that the dysmenorrhœa should be removed. A point of prime importance was the question of the justification of the local treatment of dysmenorrhœa. With regard to married patients there could be no divergence of opinion that local examination and, if necessary, treatment should in all cases be carried out. With unmarried females the lines of conduct were by no means so clear. It was impossible to separate sentiment from duty. Yet sentiment must not be considered in those patients who had to maintain themselves by their own exertions and who were incapacitated for a day or two each month. Their dysmenorrhœa prevented their taking or keeping good situations. With those women who were affluent and did not require to work dysmenorrhœa might only mean a day or two in bed with a hot bottle and the use of anodynes. But if they desired to be cured, then it seemed right to examine them under an anæsthetic and at the same time to be prepared to dilate, replace, or curette the uterus if necessary. Some objected to local treatment as it directed attention to the sexual organs, but being *hors de combat* every month during a menstrual period was surely more potent in the same direction. Another argument was that dysmenorrhœa might improve spontaneously, but so did fissure of the anus, and yet it was treated whenever complained of. Whenever drugs had failed to relieve the dysmenorrhœa then a local examination under an anæsthetic was the correct mode of procedure, carrying out any treatment that might be required.

Dr. H. M. CHURCH considered prevention better than cure and that it was the duty of guardians to be very careful at the commencement of menstrual life in the case of girls who were growing. It often happened in these days of school pressure that the education of the mind was carried on at the expense of the bodily health. This occurred more in city life than in country life and dysmenorrhœa was probably more frequent in city life. It was certainly true that dysmenorrhœa and morbid functional neuroses arising therefrom were more common in the cultured and educated classes than in the comparatively uneducated. This pointed to the desirability of a system of education less straining to the nervous system of the growing girl than it commonly was in many schools. In school life, with examinations and competitions, there was a more or less continuous excitement and strain. This affected all the secretions of the body both in quantity and quality. In the case of the uterus the disturbance might show itself in dysmenorrhœa, probably due, as Dr. Berry Hart had pointed out, to the deficient secretion from the cervix of that mucus which was believed to keep the blood of menstruation from coagulating. This would result in clotting of the menstrual blood and in the occurrence of spasmodic pain to expel it, and perhaps would be accompanied with sickness and retching. In order to prevent trouble Dr. Church recommended two or three days' rest on the sofa at menstrual periods, or if there was pain complete rest in bed where it could possibly be carried out. He referred specially to rheumatism of the uterus as a cause of pain in some cases; and if it attacked the fibrous tissue at the os internum it might lead to anteflexion. Salicylate of soda generally gave relief. In cases of dysmenorrhœa he recommended judicious cycling or gentle horse-back exercise between the periods.

Professor KYNOCH (Dundee) thought that it was important to remark that dysmenorrhœa was a symptom indicative of disease, uterine or extra-uterine or both. In young girls he did not think it was advisable to resort to any local treatment without a prolonged trial of constitutional remedies. With regard to local treatment his experience of dilatation was that rapid dilatation was not very satisfactory. These patients came back in a very short time, and dilatation was necessary again. He had now entirely given up the rapid method, using a tupelo tent which he left in for 12 hours, replacing it again for two subsequent days and plugging the uterus in the intervals with sterilised gauze. This method was more tedious but the results were more permanent, and he had not seen any bad effects from septic trouble. With regard to dysmenorrhœa due to extra-uterine affections, commonly occurring after a pregnancy, douching was very effective. But it must not be carried out in a sitting posture, which was practically useless, and the water must be hot enough to have a beneficial effect on the inflammatory processes. This temperature, as a rule, could not be borne, as the water produced so much pain on flowing over the skin as to make the patient cry out with pain. An instrument introduced by Stratz he had found very useful in allowing water at any temperature to be applied to the vagina, the return flow being prevented from touching the skin. If that failed he had had satisfactory results, and some unsatisfactory results, by opening the abdomen from the vagina and breaking down adhesions, and if necessary inspecting and treating the ovaries, &c. He had very little experience in the removal of the ovaries for this trouble. In two cases under observation just now where the ovaries had been removed for pain there

had been no improvement whatever. He would reserve removal for cases of defective development of the uterus associated with atresic conditions. In other conditions he preferred the vaginal route to the abdominal route and had obtained quite satisfactory results.

Dr. JAMES FOULIS referred to the large number of causes of dysmenorrhœa and considered that uterine treatment should only be carried out when the uterus was proved to be the cause of the pain. The question of morale always came up in the local treatment of girls, and examination was only justifiable when all ordinary remedies had failed. Many girls got well without treatment; marriage often cured them. He specially referred to the use of iodide of potassium as of great service in treating painful menstruations, giving it for several days before the period. The ovaries were often the seat of the dysmenorrhœa, and yet considerable disease of the ovary might be present without pain. Even large tumours of both ovaries might be present and yet menstruation might occur without pain. He believed that it was often ignorance of the true cause of the pain which led operators to remove the ovaries in one case and to leave them in another. Many cases had been operated upon injudiciously.

Dr. JOHN CONNEL (Peebles) had seen many cases of dysmenorrhœa even under conditions of healthy country life. He desired to emphasise the opinion that local examination should be the very last thing to be thought of in the unmarried. He knew of dozens of young women who had suffered severely and had got well somehow. He believed that the introduction of the bicycle had had more to do with the removal of painful menstruation than any other remedy he had heard of in late years. Constipation was a very common cause of dysmenorrhœa and it was often overlooked by parents in attending to the health of their daughters. As regards remedies he deprecated the use of alcohol in any shape or form; he had often found it to be the case that female drunkards had been prescribed alcohol for painful menses when they were young girls. Recently he found a young married woman being given three half-cupfuls of whisky by her relatives at her menses; she was practically drunk when he saw her. Whatever was given for dysmenorrhœa alcohol should be avoided.

Dr. J. M. MUNRO KERR (Glasgow) considered dysmenorrhœa as a symptom which was at present called a disease owing to the lesion causing it being obscure or hidden. These cases would gradually disappear so that there would be as little justification in making this diagnosis as at present there was of diagnosing "menorrhagia." The disease "membranous dysmenorrhœa" should be taken out of this class and properly spoken of as "endometritis exfoliativa menstrualis." In an analysis of 60 cases he had found an abnormally small uterus in three, stenosis of the cervix in six, and pathological anteflexion in 16. As regards stenosis it was very slight, and it was a question whether it was the cause of the pain. In treatment he favoured gradual dilatation by Hegar's dilators. No doubt in the majority of the cases the pain returned in four or five months, but it was not very trying to have the operation repeated. Electricity had occasionally been attended with good results. He had not found bleeding very successful. He had tried iodide of potassium and salicylate of sodium, but the only drugs which he had found of any benefit were antipyrin and phenacetin. He agreed with the remarks made about the use of the bicycle.

Dr. A. H. F. BARBOUR considered that operative treatment in this condition depended on the amount of the patient's suffering, and this was difficult to estimate. It depended largely on the up-bringing of the patient whether she thought a great deal about herself and magnified her ailments and suffering. If trained to think more about others and to work for them the patient did not suffer so much. In judging of the amount of pain attention should be kept on two factors—the stimulus to the peripheral end of the nerve and the irritability of the sensory nerve-centres. One of the largest benefits ever done to gynæcology had been done by Dr. Weir Mitchell, who benefited these cases so much by feeding and improving the central nervous system. He disagreed with Dr. Haultain with regard to the various operations for these cases, believing strongly in medical treatment and attention to diet at least for a few months. A course of arsenic helped very much and antipyrin could be given at the periods.

Dr. JAMES RITCHIE did not believe in local examination until every other reasonable means of treatment had been exhausted. Many cases were due to a low type of inflammatory condition and yielded to douching and ichthyol inunction, and he had known these means to suffice in cases where removal of the ovaries had been advised. The treatment of anæmia and rheumatism often relieved the dysmenorrhœa. As regards the pathology of the condition he considered that there was a periodical flushing of the pelvic organs every month and that the nervous system and vasomotor nerves had a wonderful influence over the amount, so that if the person were ill there was much more likelihood of excessive flushing from excessive dilatation of the blood-vessels. There were certain organs of which we were not conscious in a condition of health but which when they became slightly over-congested immediately became painful. In the treatment of these cases tonics were of advantage.

Dr. HOLMES (Chicago) did not believe in the mechanical theory of obstruction, as the blood that could flow through a capillary could surely pass the internal os with a diameter larger than a capillary. If clotting were present the case was altered. The amount of pain suffered depended on the amount of innervation of the uterus. He had attended a woman who never had any pain with her menses and who passed through her labour entirely without pain until there was distension of the vulva. The uterus in this case was faultily innervated; on the other hand, in dysmenorrhœa there might be excessive innervation. In the States gynæcological practice had fallen off; this was due to the fact that among American girls cycling was exceedingly common and tennis and golf also were cultivated.

Dr. J. W. BALLANTYNE considered it necessary to treat dysmenorrhœa completely till it was cured, not partially and then tell the patient nothing more ought to be done. Constipation was a very frequent cause of the trouble. The more correctly the cause was diagnosed the more successful the treatment would be. With the consent of the patient and the parents this ought to be made in every case and the proper treatment ought then to be applied; otherwise they failed in their duty.

The PRESIDENT specially referred to the appalling results that sometimes arose from the administration of alcohol to young women during painful menstruation. Local examination under an anæsthetic he considered necessary when other means failed. He did not believe that any damage could be done to a girl's feelings by an examination under chloroform at all comparable to the constant dread and anxiety with which the patient must look forward to those monthly recurring attacks. He had known many women to express the greatest gratitude for a comparatively slight operation—an amount of gratitude that might seem unreasonable unless they put themselves in their position.

Dr. HAULTAIN replied.

Professor Sänger of Prague and Professor Fehling of Halle were elected, after ballot, Honorary Fellows of the society.

Reviews and Notices of Books.

Reports from the Laboratory of the Royal College of Physicians of Edinburgh. Vol. VII. Edited by Sir JOHN BATTY TUKE, M.D. Edin., and D. NOEL PATON, M.D. Edin. Edinburgh: Oliver and Boyd. 1900.

THE present volume of these reports is considerably larger than its precedessors, probably for the reason that it is composed not of articles appearing here for the first time as in previous years, but of reprints of work which, though emanating from this laboratory, have seen the light first elsewhere. This change is perhaps the natural outcome of the multiplicity of medical publications at the present time and the not unnatural desire of writers and workers that their results shall be made public both as widely and as soon as possible. Though necessarily less interesting than fresh matter, the periodical collection of work done in individual laboratories and schools has many advantages.

The papers before us are collected into four groups according as they are physiological, anatomical, pathological, or pharmacological. The physiological section contains the great bulk of the material and serves as a monument to the energy and successful industry of Dr. Noel Paton, the superintendent of the laboratory. Both the most

important and, at this time of the year when, like everyone else, the medical man's "fancy lightly turns to thoughts" of his yearly holiday, the most interesting articles are the 18 papers dealing with Investigations on the Life History of the Salmon in Fresh Water. The first 17 of these constituted a report made to the Fishery Board for Scotland in 1898. Among the many interesting points decided in this report it appears that salmon migrate into rivers not from an urgent impulse to spawn, for their genitalia may be found in all stages of development, but because the fish tend to return to what was their original habitat after accumulating the necessary amount of food. Though they take a fly, salmon never really feed in fresh water; there is a peculiar degenerative change in the stomach and intestine of salmon during their stay in fresh water which shows that the organs are for the time functionless. Salmon return to the sea to get food, which is stored up in the body for use during their long fast in fresh water. During the stay in the sea an enormous accumulation or storage of fat takes place in the muscles; this is subsequently utilised to supply the fat of the growing genitals or is used up by the muscles.

Dr. James Dunlop's report on prison dietaries presented to the Prison Commission in Scotland is a complete and laborious piece of work, and contains as an appendix notes on the prison dietaries of other countries. Among the other varied papers that are to be found in this report reference should be made to a valuable series of articles on animal pigments by Miss Newbigin, and to further papers inspired and in part contributed by Dr. Noel Paton.

Encyclopædia Medica. Under the general direction of CHALMERS WATSON, M.B. Edin. Vol. IV.: Foot to Hernia. Edinburgh: William Green and Sons. 1900. Pp. 534.

THE fourth volume of this extensive undertaking appears well up to its promised time and contains a number of authoritative articles written by recognised experts. Thus the editor is to be congratulated on the success that has attended his efforts in obtaining the services of Mr. Mayo Robson as a contributor on Diseases of the Gall-Bladder and Bile-ducts, of Dr. Dawson Williams on Glandular Fever, of Dr. David Newman on Hæmaturia, and of Dr. Graham Steell on Diseases of the Myocardium and Endocardium. It is impossible even to refer to all the articles, but it is only right to draw attention to some of the more notable. Dr. G. F. Still, who is well known in connexion with his careful pathological work on diseases of children, has wisely been chosen to write on the Gastro-intestinal Disorders of Infancy and has admirably justified his title thereto. Dr. A. E. Garrod's name is so rightly associated with modern knowledge on urinary pigments that it is satisfactory to find that he is responsible for the articles on Hæmoglobinuria and Hæmatoporphyrinuria. The heart is fully treated in this volume and an extremely careful and accurate contribution on its pathology is provided by Dr. T. N. Kelynack, who is associated with his former teacher and present colleague, Dr. Graham Steell, in the valuable section on diseases of the myocardium and endocardium. Lastly, while congratulating Dr. Watson on his success in an editorial capacity, we must compliment him on his admirable contribution on the important subject of Gout.

Annual and Analytical Encyclopædia of Practical Medicine. By CHARLES E. DE M. SAJOUS, M.D. Vol. V.: Methyl-blue to Rabies. Philadelphia, New York, and Chicago: The F. A. Davis Company. 1900. Pp. 662.

THE present instalment of this useful book of reference bears the date of October, 1899, and contains, in addition to a succinct account of the subjects treated, references to the literature of the three years 1896–97–98. Each article is complete in itself, and though it embodies, does not confine itself to, the advances of comparatively recent years. In these days of specialism the present volume must have been a laborious one to bring out, for it includes many specialties—otology, laryngology, neurology, obstetrics, ophthalmology, pediatrics, &c., in addition to subjects classed under general medicine and surgery. The printing and general appearance of the work are fully up to the standard of the preceding volumes, and, like them, volume V. will serve as a useful source of reference.

Progressive Medicine. Vol. I., March, 1900. Edited by HOBART AMORY HARE, M.D., assisted by C. A. HOLDER, M.D. London: Henry Kimpton. 1900. Pp. 428. Price 12*s.* 6*d.*

THIS is the first volume of the second year of Dr. Hare's summary of current medical literature, and is planned to provide the busy practitioner with an account, not of everything that has been written, but of those contributions that really mark an advance and are worthy of his time and attention.

In the surgery of the head, neck, and chest there is a useful *résumé* of the operative treatment of tuberculous disease of the lung. The next section, on infectious disease, including acute rheumatism and pneumonia, under the care of Dr. F. A. Packard, contains a coloured plate of Koplik's spots on the buccal or labial mucous membrane—the pathognomonic sign of measles. Dr. Blackadder has put together a very readable and interesting account of the recent work in diseases of children, while the account of the last year's advance in pathology by Dr. Ludvig Hektoen covers a great deal of ground and contains a large amount of interesting information. The volume closes with two reports on the Progress of Laryngology and Rhinology by Dr. Logan Turner of Edinburgh, and on Otology by Dr. Randolph of the Johns Hopkins University, Baltimore. In conclusion, the editor may be congratulated on the continued success of this useful medical quarterly.

LIBRARY TABLE.

The Standard Intermediate-School Dictionary of the English Language. Designed to give the Orthography, Pronunciation, Meaning, and Etymology of over 38,000 Words and Phrases in the Speech and Literature of the English-Speaking Peoples. With 800 Pictorial Illustrations. Abridged from the Funk and Wagnalls Standard Dictionary of the English Language by JAMES C. FERNALD, Editor of the Students' Standard Dictionary; English Synonyms, Antonyms, and Prepositions; The Spaniard in History, &c. London: Funk and Wagnalls Company. Price 4*s.*—This dictionary is certainly in many ways a remarkably good one. It is not, of course, satisfactory in every way, as, for instance, in the definition of the word "camel," although a good illustration is given of the Bactrian or two-humped camel of Asia no mention is made of the fact that the African variety has but one hump. This variety is given under the word "dromedary." Again, under the word "spider" we find the following: "An insect-like creature that spins a thread and makes webs to catch its prey." We cannot agree that a spider is an insect-like creature, neither do all spiders make webs to catch their prey, as the definition would probably convey to one who did not know. On the whole, however, the book will be found very useful and we are glad to see that in the illustrations of animals the amount of reduction is given.

For Britain's Soldiers. By RUDYARD KIPLING, S. R. CROCKETT, Sir WALTER BESANT, and others. Edited by C. J. CUTCLIFFE HYNE. London: Methuen and Co. 1900. Pp. 315. Price 6*s.*—Detailed criticism is out of place with regard to a book like this one, for all the stories were written by their respective authors as a contribution to the war fund, while the publishers are giving all the profits for the same object. But we may say that all

the stories are eminently readable and some are remarkably good. Mr. Rudyard Kipling introduces us to the son of the immortal Estreekin Sahib whom we all admired in the "Mark of the Beast." Adam is, indeed, his father's son, and one to be proud of. Sir Walter Besant supplies an interesting little study in psychology and Mr. A. E. W. Mason gives us as creepy a story as ever was written. The art of horrifying by the use of the indefinite is not within everyone's power, but Mr. Mason's account of the ride through that dreadful ravine ranks with the closing scenes in Lefanu's "Watcher," with that awful scene in "Dr. Jekyll and Mr. Hyde," where the butler and Mr. Urmson stood outside the locked door, and with the nameless horror of Miss Violet Hunt's "Story of Mrs. Arne." The book is one for holiday-makers to read.

JOURNALS.

Caledonian Medical Journal.—In the July number Mr. Alexander Macdonald of Inverness concludes his articles on the Ethnology of the Scottish Gael, the first of which was noticed in THE LANCET of April 21st (p. 1139). About the sixth century there were three principal kingdoms in Scotland—namely, the Pictish kingdom on both sides of the Grampians; the kingdom of Strathclyde, occupying Mid-South Scotland; and the kingdom of the Scots (who had come over from Ireland) in the south-west. The Picts were, he believes, an early offshoot northwards of Britain's (i.e., England's) earlier settlers who not improbably came into Scotland when another section of the same people migrated into Ireland. A few centuries later the Scottish Gaels might be resolved into two nearly equipotent races—(1) the Brito-Scottic, or early Celt, of dark hair, dark eyes, dusky skin, and small limbs; and (2) the fair or xanthous Celt, of fair or flaxen hair, blue or light-grey eyes, clear skin, and large limbs. In conclusion Mr. Macdonald describes at considerable length the facial characteristics of the modern Highlanders, classifying their features as "Ibero-Celtic," "Germano-Celtic," and "Scandinavian Celtic."

Dublin Journal of Medical Sciences.—The original communications in the July number are on Epidemic Cerebro-Spinal Meningitis, by Dr. H. C. Drury; on Epidemic Cerebro-Spinal Meningitis in Dublin, by Dr. A. R. Parsons; and on the Symptoms or Phenomena formerly known as Croup, by Mr. Langford Symes.

New Inventions.

AN APPLIANCE FOR DEODORISING ESCAPING SEWER GAS.

THE disgusting emanations which escape from fresh air drain inlets or from sewer ventilators, whether from the gratings in the roads or from shafts against buildings, are a constant source of annoyance and very often also of ill-health. Several attempts have been made, with more or less success, to render these aereal effluents innocuous. The latest addition to these contrivances has just been submitted to us by the inventors, Messrs. Bostel of 73, Ebury-street, S.W. It consists of a metal box about four inches square which fits over the inlet pipe having a grid on one side. Internally the box contains a glass dish filled with some non-corrosive disinfectant. For this purpose pine oil is to be recommended, for in addition to its pleasant smell this oil does undoubtedly absorb oxygen which it gives up again in contact with foul gases, thus destroying their noxious and unpleasant character. Behind the face of the grid is a screen composed of a number of small woollen wicks the lower ends of which rest in the disinfectant which ascends the wicks and keeps them loaded by capillary force. The air passing in or out through the grid travels through the screen and comes into intimate contact with the disinfectant, and thus the foul emanations are cleansed. The idea is certainly ingenious and so long as the apparatus is attended to its object will be gained. Every part is easily accessible, so that no difficulty need be experienced in keeping it in order. A small apparatus constructed on a similar principle is made for the diffusion of a volatile disinfectant in the air of the water-closet or other places where unpleasant smells are in evidence. The apparatus is inexpensive, is in use in our offices and elsewhere, and has given every satisfaction. It certainly appears to provide a much needed accessory to our systems of sewer ventilation both on the domestic and the large scale.

THE THIRTEENTH INTERNATIONAL CONGRESS OF MEDICINE:

A LAST WORD.

THE Thirteenth International Congress of Medicine will be held at Paris from August 2nd to 9th inclusive.

HOW TO BECOME A MEMBER.

Every duly qualified medical man wishing to become a member of the Congress must send to the offices of the Congress at 21, rue de l'Ecole de Medécine, (1) his name, Christian name, and qualifications; (2) his address; (3) his subscription of 25 francs; and (4) a note showing to which section he wishes to be inscribed as belonging. Names can be sent in up to the date of opening of the Congress, but in order to obtain railway facilities they had better be sent in as soon as possible.

PROGRAMME OF THE CONGRESS.

The Congress will sit every day except on Sunday, August 5th, and hold either general meetings or sectional meetings.

A. *General meetings.*—These meetings will be three in number and will unite all sections of the Congress. They will be devoted to the customary addresses and to the passing of the usual votes. (No one can deliver an address at a general meeting unless he has been previously invited to do so by the Executive Committee.)

B. *Sectional meetings.*—These meetings will be held every day. They will be devoted to the reading of papers and to discussions thereupon. Any member can take part in any of the work of any section whatever be the one to which he shall have been formally allotted.

C. *Visits to hospital and laboratories.*—Some sections have organised visits to the above establishments for certain days and at certain times. But in addition to these corporate visits members of the Congress are at liberty to visit any hospital or laboratory which they may choose.

Fêtes.—We have already given a list of the fêtes to be held during the Congress in our issue of July 7th, p. 34.

The *railway arrangements* for British members were published in our issue of July 14th, p. 127.

THE GENERAL MEETINGS.

So far the arrangements are as follows:—

At the *first general meeting* to be held on August 2nd at 2 P.M. in the Salle des Fêtes de l'Exposition, with the President of the Republic in the chair, the following addresses will be delivered:—Official addresses: (1) address by the President of the Congress; (2) report of the General Secretary of the Congress; and (3) addresses by the delegate members of foreign Governments. Scientific addresses: (1) address on Traumatism and Infection, by Professor Virchow; and (2) address on Experimental Therapeutics as a New and Fertile Method for Physiological Research, by Professor Pavlov.

The *second general meeting* will be held on August 6th at 2 P.M. in the large theatre of the Sorbonne, when the following papers will be read:—Professor Baccelli, On the Treatment of Tetanus by Hypodermic Injections of Carbolic Acid; Professor Sir J. Burdon Sanderson, Some Pathological Problems of To-day; Professor Jacobi, Medicine and Medical Men in the United States; and Professor Albert, On the Architecture of Bone in Man and in Animals.

The *third general meeting* will be held on August 9th at 2 P.M. in the large theatre of the Sorbonne, and the business will be as follows: award of the triennial prize founded in 1897 and given by the city of Moscow; announcement of the place of meeting and the names of the officers of the Fourteenth International Medical Congress; and declaration of the closing of the Congress.

THE LANCET.

LONDON: SATURDAY, JULY 28, 1900.

THE CENTENARY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IN March, 1800, the Royal College of Surgeons of England received from GEORGE III. its first charter and during the present week the College has been celebrating the hundredth anniversary of its foundation. The history of the granting of the Charter and of the College during these 100 years is not without interest.

Towards the end of the eighteenth century the old Company of Surgeons came to a somewhat inglorious end through the illegal action of part of its governing body, and an attempt to reconstitute it by an Act of Parliament in 1797 was thrown out at its last stage; but three years later the Royal College of Surgeons was established by a Royal Charter. To it was intrusted the care and maintenance of JOHN HUNTER'S museum. The members of the Council under this Charter of 1800 were elected for life and filled any vacancies which might occur in that body by coöptation and by such a method of election it cannot be supposed that a very efficient governing body would be obtained. The museum and library were not utilised as they deserved. The museum for many years was uncatalogued and was open to the Members only during four months of the year, and then only for four hours each day. To the library the Members of the College were not admitted at all. These were only a few of the evils under which the College laboured. Reform in some measure gradually took place and the rights of the Members were recognised to a slightly greater extent; but it was felt that while the constitution of the College remained unaltered no thorough improvement could be effected. At last, after years of discussion and of debate, the Government decided to make the Council an elected body, but it was thought undesirable to confer the franchise on the whole body of Members, and therefore it was decided to create a new body of Fellows, to whom should be intrusted the right to elect members of the Council. Members of the College were to attain to the higher rank of Fellows by examinations of increased severity, but the first Fellows were all elected to that dignity from the general body of Members. It is under this constitution that the College at present exist and that it has merits cannot be denied. The number of Fellows has greatly increased, so that they now exceed 1200, but even at the present day the constitution of the College is oligarchical and the government is even narrower than it appears, for many of the acts of the College, which should be the work of the Fellows at least, if not of the Members, such as the election of the President and the appointment of the representative on the General Medical Council, are performed by the Council itself. The stream of reform in the College, however, still flows on, if slowly. Year by year greater concessions are granted to the Fellows and the Members. The museum is now open for nearly the whole year and for many hours a day. Every year at a general meeting of the Fellows and Members the Council presents a statement of the work done during the past year, and although these meetings have no legislative or executive power, yet their very existence forms a tacit acknowledgment of the right of the Members to a share in the body corporate. The tone also of the Council is changing and we may look forward with confidence to seeing at no distant date the Members allowed a part in the government of the College. Brief though this sketch of the history of the College may be, yet it will serve to show that substantial progress has been made in converting the institution set up in 1800 into a College of Surgeons founded on a broad basis of justice to all the constituents of the body corporate. Of the many other internecine conflicts that have occurred it is unnecessary now to speak. Suffice it to say that the original *non possumus* attitude of the Council is passing away. Slowly and reluctantly it yields to the steady pressure of modern thought and feeling.

Whatever opinion may be held as to many of the acts performed during its corporate life—and few indeed will be found willing at the present day to support all the actions of the Council during the early years of the century—all will agree that the Royal College of Surgeons of England is a most important element in surgical education and examination in this country. Although it is only one out of 22 examining bodies in the British Isles which have the power of conferring a licence to practice, yet it is probable that there is no body which exceeds it in beneficial influence on surgical knowledge at the present day. In two respects it is practically unequalled.

In the first place the unrivalled museum is a collection of which any institution might be proud. It is founded on the specimens prepared by JOHN HUNTER at an enormous expense. These were bought by the Government for £15,000 at HUNTER'S death and they were given into the custody of the Royal College of Surgeons. The collection has been greatly increased so that the preparations at present exceed by many times the original number. They include specimens connected with normal human anatomy and with pathology, anthropology, and zoology. There is also a very elaborate series of specimens illustrating physiology. It may safely be said that there is no other museum like it in the whole world.

The library also, though perhaps not quite so peerless as the museum, contains an exceedingly good and extensive collection of books connected with medicine and the allied sciences.

The work of the College in surgical education has been great in the past; it may well be much greater in the future. Let the Council make such arrangements as shall utilise to the full all the teaching power of the museum and the library; let there be established in addition to the few lectures given now to scanty audiences series of lectures on special branches of surgery, anatomy, and zoology, to be illustrated by the specimens from the museum. In this way the teaching power of the College could be greatly increased in addition, and not in opposition, to the ordinary lectures of the medical schools of London.

On the occasion of the centenary celebrations honorary diplomas have been conferred on the PRINCE OF WALES,

the Marquis of SALISBURY, the Earl of ROSEBERY, and many eminent men of this country and from abroad, and for this purpose a special supplementary Charter was obtained.

Although on many occasions we have felt it to be our duty to point out faults in the management of the College, yet we confess that in spite of all its faults—and they are many—we are proud of possessing in this metropolis of the world an institution like the Royal College of Surgeons of England.

THE starting-point of the wide discussion of the pathology of the nervous system presented to us in Dr. MOTT'S lectures[1] is the nerve-cell, the central nutritional element of the neuron. The peculiar granules revealed in its substance by basic staining agents, the method of NISSL, he regards as revealed, but not actually produced, by the influence of the hardening process. When the cells have been stained during life the granules are invisible, but this only shows that the hardening agent has increased the contrast between tissues that present a chemical and functional difference during life which is augmented by the process to which they are subjected after death. These Nissl granules are of great pathological importance on account of the changes they present in many conditions. They seem to consist of a nucleo-proteid substance which is precipitated in hardening, and is regarded as lying between the nerve fibrils which pass through the cell; it seems to be a protoplasmic substance intimately related to the nucleus of the cell and to its vital function. A change in the appearance of these granules and their coalescence attend most important functional alterations, and when they unite, so as to fill the cell with a mass homogeneously coloured, the conducting fibrillæ are apparently so far damaged as to be no longer capable of function.

The investigations of WALLER not only revealed the dependence of the nutrition of the nerve-fibres on the cells from which they proceed, but, as Dr. MOTT shows, he distinctly anticipated the conception of the functional units which is the essence of the neuron theory. Later research has shown that the section of the axis-cylinder has an upward influence on the cell, although far slower and slighter than that on the peripheral part of the nerve. This upward influence was, indeed, observed as a late result of amputation by Dr. W. H. DICKINSON long before the modern means of discerning the early and slighter changes in the nerve-cells were available. These changes are remarkable. After experimental division of the nerve the protoplasmic granules which stain so readily no longer remain distinct and the nucleus is displaced towards the periphery of the cells. A similar change is observed in cases of peripheral neuritis in which the axis-cylinder perishes at a distance from the cell. If recovery is possible the cell increases in size, the staining material resumes a more normal aspect, and the nucleus regains its central position. Ultimately the normal aspect returns after the nerve fibre has regenerated. The enlargement of the cell is regarded as evidence of physiological activity connected with the increased trophic energy. If the damage to the nerve is too severe to be recovered from, slow progressive changes occur in the proximal part of the fibre, with diminution of the myelin, and ultimately changes in the axis-cylinder and the alterations in the nerve-cell, instead of diminishing, progress to atrophy.

The slighter but definite changes in the nerve-cells when the nerve-fibre recovers have an interesting practical application which it was perhaps beyond Dr. MOTT'S province to notice. After recovery from pure peripheral inflammation such as that of the facial nerve, which causes the common form of facial paralysis, a remarkable over-action invariably ensues, in consequence of which there is undue tonic contraction of the muscles, sometimes accompanied by clonic contractions, and an associated over-action between the upper and lower parts of the face. It has been recognised that this must be ascribed to a morbid state of the nucleus, secondary in some way to the disease of the nerve trunk. The observed changes in the cells are important in this connexion. The associated over-action is, however, of muscles too distant to be explained by the changes in the individual cells, but the dendrons which convey the impulses to the cells must share the disorder of nutrition of the latter, and we are thus able to perceive a possible mechanism for this peculiar symptom, which has also been observed as a sequel to paralysis of the nerves of the arm.

Dr. MOTT'S observations on the appearances in the nerve-cells of the brain in experimental anæmia, which is soon relieved by the collateral circulation, are of considerable interest. He finds the transient disturbance of function is associated with swelling in the cells, an alteration in the arrangement of the staining Nissl granules, and a displacement of the nucleus towards the periphery of the cell, which may proceed to its extrusion and the death of the cell. The amount of destructive change can be traced by subsequent degeneration of fibres in the spinal cord. The slighter alterations gradually pass away if the circulation is soon enough renewed, and the several degrees of change closely resemble those which have been found in experimental anæmia of the spinal cord, according to its duration and in correspondence with the transient or permanent paralysis of the limbs which results. Another instructive subject is the influence of temperature on the nerve-cells. Their condition in cases of hyperpyrexia in the human subject shows a remarkable correspondence with those which have been found in animals that have been exposed to heat. In proportion to the degree and duration of the temperature there is the same confluence of the Nissl granules above described, indicating a profound alteration in the protoplasmic constitution of the cell. In man, however, the conditions found may be sometimes in part ascribed to the toxic agent which causes the high temperature. The proteid constituents of the nervous matter coagulate at different temperatures, and it has been found that one of the most important of these coagulates at a lower temperature if the exposure is more prolonged. A slighter degree of pyrexia for a longer period causes the same change as a higher degree for a shorter time. Thus, chemical investigations throw some light on the processes observed in disease. Moreover, it has been found that a slight degree of the change induced by hyperthermia is compatible with recovery, as is the

[1] See also leading article, THE LANCET, July 21st, 1900, p. 198.

similar change observed after injury to a nerve, and Dr. MOTT suggests that this may indicate a mode in which the cold bath effects its beneficial influence by reducing the temperature before its effects have continued so long as to preclude recovery.

The influence of toxic agents in causing degeneration of the neuron is perhaps the most important part of the subject from a practical point of view. It is this influence which has led to the wide extension of our knowledge of the mechanism of disease and the causes of symptoms. The toxic agents may be derived from without or may be generated in the body by micro-organisms or by perverted normal processes. The special selective influence of these toxic agents on certain parts of the nervous system is a familiar and special feature of their action of which Dr. MOTT gives many striking illustrations. As he insists, it shows that the tissue of the nerve structures of different function presents some slight modification in constitution which involves a different susceptibility. A striking instance of the difference in selective action which is caused by a most trifling difference in chemical composition is the discovery of Dr. A. WALLER that the difference of a molecule of water determines the action of one poison, veratrin, on the muscle or on the nerve. One of the most striking instances of local influence is afforded by the poison of tetanus. The affinity of this for nervous matter is strikingly shown by the fact that it loses much of its poisonous power if previously made into an emulsion with nerve substance. There is much discrepancy of observation regarding the occurrence of changes in the nerve-cells of the spinal cord after death from the tetanus toxin, a fact which may find its explanation in the chief action of the poison on the extremities of the dendrites.

The study of the chemistry of nerve degeneration has yielded interesting results, some of which are perhaps still open to the criticism which very few are qualified to afford. One practical point on which Dr. MOTT brings forward some weighty evidence is the probability that some of the symptoms in diseases attended with rapid nerve degeneration are due to the toxic influence of the products of the nerve tissues themselves. Choline, which seems to be a normal product of the metabolic changes in the nerve structures and is produced normally in small quantities and passes out of the system probably as urea, is found in general paralysis in amounts large enough to cause its characteristic effect of lowering the blood-pressure. Another product, neurine, which is thought to be sometimes produced in degeneration, has highly toxic qualities. The amount of proteid matter in the cerebro-spinal fluid in general paralysis is three times the normal and experiments seem to show that it would favour an occurrence of congestive stasis and even thrombosis in this disease. Dr. MOTT is inclined to attach much weight to this influence in causing special changes in the frontal and central convolutions because the veins from these ascend into the longitudinal sinus, and even open into it, so that the blood from them enters in a direction opposite to the current in the sinus. But it is to be noted that the current in this part of the sinus is very feeble and the influence of the descending blood in the posterior part is probably sufficient to prevent much tendency to stasis. If the mechanism were really effective, actual thrombosis in the veins of this part should be a more frequent incident in general paralysis than it is.

The close pathological relationship of general paralysis and tabes, which has been widely recognised, and formed the subject of a discussion at the Pathological Society which was opened by Dr. MOTT, is discussed in his fourth lecture. It is more than 20 years ago since WESTPHAL pointed out the frequency with which the posterior columns of the cord are degenerated in general paralysis of the insane, and the frequency with which the symptoms of the two diseases are combined, the frequency with which those of one or the other predominate or are chiefly manifested in the early stage of the disease, has been repeatedly noted. In the cases in which the combined symptoms are present, some special symptoms characteristic of tabes may occur in general paralysis when pronounced tabetic symptoms are absent. Of this Dr. MOTT gives many striking illustrations. The occurrence of loss of the reflex action of the iris to light has been frequently observed in general paralysis, and some instances are given of perforating ulcer of the foot and of tabetic arthropathy in this disease. In many of the combined cases in which the symptoms of tabes lead the way, these continue slight, remaining in the "pre-ataxic" stage after the mental affection has developed. The lecturer has had a unique experience of juvenile general paralysis and finds it associated with congenital syphilis just as juvenile tabes is known to be. He regards the two diseases—tabes and general paralysis—as really one, affecting sometimes the neurons which associate different parts of the central and frontal convolutions and in others the neurons of the posterior ganglia of the cord. The only objection to this which can be taken depends on the conception attached to the word "disease" and on the importance to be given to distinctive symptoms presented by a similar process in different regions.

There is, of course, a very large amount of assumption in Dr. MOTT'S lectures, and its quantitative estimation is a task for which very few can present the requisite knowledge. This does not lessen their value, because a careful reader can discern where the process comes in. Suggestion is precious if only it is taken as it should be—as an indication of the direction in which to look for truth. The field of science which he has ploughed with remarkable skill is in the most advanced region into which pathological knowledge has penetrated. It is certain that his lectures, fruitful as they are, will have far more prolific results from the investigations to which they will give rise.

But their admirable character and the manifest extent to which they are dependent on the opportunity and facilities afforded by the arrangement of the London County Council excite in us one regret. We should like to see the therapeutics of insanity investigated in a manner equally thorough and equally scientific under the same auspices. At present individual symptoms are relieved and all available external circumstances are combined to facilitate recovery, but how seldom is any systematic effort made to influence the course of disease by medicinal treatment. It is regarded as useless, and the belief that it is so is the cause of the absence of effort. The experience of many physicians outside

asylums testifies to the fact that even in general paralysis wisely ordered medicinal treatment is not seldom strikingly beneficial, but we hear little of attempts thus to influence the disease in asylums. The lectures of Dr. MOTT contain abundant evidence of the influence of certain definite substances of known chemical composition in causing disease. There is sufficient evidence also that drugs of definite composition may be employed to relieve or cure disease. We confess that we should be glad to hear that the London County Council has ordered a wing of one of its asylums to be set apart for cases, carefully selected, each one of which should be subjected to systematic treatment by suitable chemical agents, the results of which should be closely and persistently observed, recorded, and ultimately reported for the general good. No doubt most alienists will regard the suggestion as visionary, but we do not doubt that many of our readers who have had opportunities of observation will agree with us that the results would not improbably justify its adoption.

ALL members of the medical profession in this country must feel desirous of seeing the matters in dispute between the Council of the British Medical Association and a large section of the members of the Association amicably settled. Even the most advanced members of this section would disclaim any wish to weaken the power of the Association or to diminish its numbers. But the difference of opinion between the Council and those who succeeded in defeating it at the special meeting in Exeter Hall on July 18th is considerable and this fact must be faced. It does not seem to us that matters are incapable of adjustment if a little moderation on both sides be observed and clear ideas be kept in the ascendant as to the nature and the objects of the Association. The general meeting at Exeter Hall had an importance which general meetings of the Association, and conspicuously the general meetings of the annual congress, have not often had. It had the importance of numbers, coming in this respect nearer to what a general meeting of an association with 17,000 members or more should be. Comparatively small numbers always assemble at general meetings of the profession to discuss alleged grievances—a fact which shows that after all we are a profession and not a trade and that scientific and professional questions have a charm for us that ethical and social questions have not. At the annual meetings of the Association it is difficult to get a general meeting together with a larger attendance than 50 or 60. Dr. J. R. THOMSON, the chairman of the Council, says that 30 is a good average attendance for these general meetings. But at the Exeter Hall meeting last week there was an attendance of 270 or more when the Council failed to obtain the requisite majority of three-fourths for the adoption of the new Articles of Association.

We need not here enter into all the details of difference between the Council and those who defeated it, but it would be foolish to make light of the difference or to neglect any reasonable means of removing it. The essence of the difference is that the Council think it best for the Association that the management and control of the business and affairs of the Association, including the disposition and expenditure of its funds, should rest with the Council, while the majority of the members present at the Exeter Hall meeting consider that the individual members of the Association acting through general meetings should have more power. The Council at the Exeter Hall meeting submitted a new set of regulations embodying their views and the thirty-fifth clause of these new articles[1] is the one round which the chief contest rages. This clause gives to the Council the important powers to which we have alluded, vesting the whole business conduct and pecuniary discretion of the Association in the Council practically without appeal. It is very natural that the members should wish for more powers, but it is obvious that these can only be exercised mediately. 17,000 men cannot all govern an association. Some means must be found of easily ascertaining the views of the majority of the members and of securing for them complete expression in the Council. The difficulty is to ascertain what the real majority of members actually think. A mere general meeting does not necessarily help much towards finding this out. As we have seen, these meetings are generally scantily attended, and are not unfrequently monopolised by a few louder voices. Of one thing we are certain. To make the Council mere delegates, every councillor being pledged to vote in accordance with the views of his constituency, would be an unsatisfactory way of governing the Association. Men who have to give the last judgment on a question of importance should be in a position to hear all sides of it and to decide accordingly. For a member to issue a post-card to the Council with a cut-and-dried deliverance on a difficult question and for this deliverance to bind the executive of an association with 17,000 members would be an easy and flattering way of governing so far as the member is concerned, but not one that would be likely to conduce to the moral, scientific, or financial reputation of the Association.

A few well-attended general meetings at which some plain speaking on both sides might be advisable, would do much to effect a reconciliation of view between the Council and the members. It will probably be found that the best way of increasing the attendance at general meetings and their authority will be to hold them separately from the annual meeting at some convenient centre. The Ipswich meeting will have a great advantage in following so closely on the discussion at Exeter Hall, and it is to be hoped that all parties will come together with a disposition to find a *modus vivendi* which, while securing respect for the opinion of members of the Association, will leave the chief control over its business and expenditure with the Council. There is no derogation from the function of members in leaving such control with the Council so long as members have due control over the election of the Council, any more than it detracts from the English constitution that the House of Commons has control over the public purse. The number of the Council exceeds that of the average general meeting, and it is an elected body representing more or less all the members. Such a body cannot be called an autocracy or

[1] See Brit. Med. Jour., July 7th, p. 54, et seq.

an irresponsible junto. It will not conduce to the stability and influence of the Association to lessen the responsibilities of the Council or to make it too easy for a small number of members to tamper from time to time with its regulations and by-laws. And as long as general meetings are so sparsely attended their views must be regarded as the views of a small number.

THE First International Congress on Medical Ethics or Deontology commenced its sittings in Paris on Monday, July 23rd, and comes to an end to-day, Saturday, July 28th, thus overlapping the Congress of the Medical Press and impinging upon the great International Congress of Medicine. The plethora of congresses arranged to take place in Paris during the end of July and the beginning of August should have led to larger attendances for the view that the medical man interested in any one of them, finding himself in Paris, would inevitably attend them all, was a probable one. As a matter of fact, however, a great many medical men, especially English medical men, have been frightened away by the fear of finding Paris over-full of the medical world. In England other abstentions have been due to the fact that the British Medical Association meets at Ipswich during the first week in August and also to a widespread feeling that the attitude of France, especially of Paris, is so inimical to England that the Englishman is better away from the beautiful city of pleasure. We trust that even if the attendance be a little sparser than was expected the proceedings at the Congress of Deontology will be thoroughly successful, for the work that it proposes to do lies very near our heart. It is impossible that a body of earnest men, attending either as delegates from ethical bodies or on account of their own individual work in ethical fields, can deliberate carefully upon the important practical questions comprised under the phrase "deontology" without some good accruing to the medical profession. We are aware that the different customs of different nations no less than the various ways of regarding social problems of all sorts preclude any idea of an international code of medical ethics being established; but medical men of all nations will be benefited by learning what situations are created in other countries than their own by hospital abuse, by quackery, and by lay exploitation. On p. 275 of our present issue will be found a report from our special correspondent of the proceedings at the First International Congress on Medical Ethics, and the success that has already attended the formation of medical unions in Austria and Belgium should encourage those members of the British medical profession who have made practical attempts in this country to the same end.

Annotations.

"Ne quid nimis."

THE PATHOLOGY OF INSOLATION.

AT a recent meeting of the New York Academy of Medicine Dr. Ira van Gieson read a paper on sunstroke, a subject which has just now a special importance. The pathology of this affection was still unknown. The symptoms and manifestations had interesting resemblances to those of poisoning by snake venom, while the loss of consciousness and the convulsive and tetanoid seizures brought it into relationship with the coma of diabetes and uræmia in particular. Among the pathological theories two occupied a prominent place. The caloric theory stated that the symptoms were due to the direct action of excessive heat on the body, and important facts illustrating or confirming this view were furnished by the experimental investigations of Goldscheider and Flatau, Ewing, and others, who had found certain characteristic (destructive) lesions in the cerebral and spinal nerve-cells of animals submitted to artificial hyperthermia which ended fatally with symptoms resembling those of sunstroke. Dr. van Gieson points out that these changes might be secondary to changes in the blood brought about by exposure to the excessive heat to which these animals were subjected. The toxic or autotoxic theory sought to trace a toxic agent which circulating in the blood acted on the nerve-centres as a poison. He stated that his investigations and experiments at the Pathological Institute in New York during the epidemic of sunstroke in 1896 convinced him that the disease was due to an acute toxæmia originating somewhere in the body and acting violently on the nervous system, particularly on the cells which governed the heart and controlled the vaso-motor apparatus. The delirium, convulsions, opisthotonos, and mental derangement could be partly explained as the outcome of such a poisoning of the nerve cells by an agency of autogenous origin. In cases which resulted in recovery within a few hours there was probably very little degeneration of the ganglion cells. Between this grade and that in which the cells were permanently damaged there were probably many intermediate conditions. "The source of the poison, as well as its relation to the cessation of perspiration prior to and during the attack, were unknown. The sudden onset of the disease favoured the autotoxic theory." Experiments on animals made by Dr. P. A. Levene showed that the blood of patients suffering from insolation contained a poison the virulence of which was as great as that of some snake poisons and in some respects resembled their action. The urine of convalescent patients when injected into the circulation of rabbits was found to produce decidedly toxic results, and injections of blood serum taken from two patients gave prompt and decisive results. The two classes of animals which perspired most—viz., human beings and horses—were the ones which showed the most marked classical symptoms of sunstroke. Probably the pathogenesis of sunstroke could be formulated somewhat as follows. The exciting cause in the form of excessive external heat induced a change in the blood the nature of which was unknown. As a result of this an angio-paresis resulted, this being probably caused by a paralysis of the vaso-constrictor nerves due to the toxic action of the altered blood. The cessation of perspiration in the subject of sunstroke and the accumulation of carbonic oxide in the blood were concomitant with the angio-paresis. With the angio-paresis and the accompanying stasis of blood in the vessels began the hyperpyrexia, for they interfered with the free radiation of heat from the cutaneous surfaces to the extent of 80 or 90 per cent. The toxic condition of the blood acting upon the cerebral nerve-cells produced loss of consciousness. The best working hypothesis, sustained to some extent by the few facts definitely ascertained, pointed to an auto-intoxication of somewhat sudden origin. It was interesting to observe that as in the cases of persons dying from snake-poisoning the post-mortem clotting of the blood was retarded. In the discussion following the reading of the paper Dr. P. A. Levene observed that in sunstroke there were a marked diminution of the urine secreted (ischuria), a decrease in the quantity of urea and other ingredients, and the specific gravity of the urine was lowered. This fact could not be explained by postulating an organic change in

the kidneys, such as parenchymatous nephritis, as no albumin or casts could be detected in the majority of cases. Pfaff of Harvard had recently demonstrated that defibrinated blood influenced the function of the kidneys in a similar manner to that produced by sunstroke. This would suggest that extreme heat produced changes in the blood similar to that produced by defibrination, or probably even rendered the blood less coagulable than normally. The latter fact was observed by some pathologists in cases of sunstroke and would be a corroboration of the autotoxic theory. Dr. George M. Parker, who was a resident physician in hospital at the time of the epidemic of sunstroke in 1896, said that the mortality was 66 per cent., death occurring in from 12 to 36 hours after the onset of the attack. The symptoms were those of an acute general poisoning. Comparatively few cases of sunstroke occurred until the hot weather had lasted for several days. Dr. Charles A. Whiting, referring to the same epidemic, emphasised the statement that the cases were rare during the first two or three days of the hot spell and then began to multiply rapidly.

THE RELATIVE VITIATION OF THE AIR OF ROOMS PRODUCED BY VARIOUS HEATING AND LIGHTING APPLIANCES.

"WHEN a coal fire is in use for heating and the electric light for lighting an inhabited room the air is purer than by any of the other plans tried for heating and lighting." Such is, perhaps, the most important conclusion arrived at in an interesting investigation on this subject by Mr. Francis Jones, F.R.S. Edin., F.C.S. The results are published in a *brochure* which has recently reached us. This conclusion may have been anticipated when the conditions described are considered. But Mr. Jones's investigation has led to other observations which are not less in point of interest as bearing upon the question of the healthy condition of domestic apartments. He finds, for instance, that the air of a room, however heated and lighted, is purest at the floor, less pure three feet above, and most impure at the ceiling, and that when a gas fire is in use for heating and the electric light for lighting the amount of carbon dioxide in the room rises rapidly in the first two or three hours and then remains uniform for three or four hours afterwards. When a coal fire is in use and an ordinary gas-jet is burning the air of the room is purer than when a gas-fire is in use and an ordinary gas-jet burning. The use of a gas cooking-stove with a flue connected with the chimney greatly raises the amount of carbon dioxide in the air of the room. The humidity of the air of the room is much diminished by the use of gas fires. We do not find any reference to the work of THE LANCET upon this subject, but if Mr. Jones will refer to the report of THE LANCET Special Analytical Sanitary Commission published in THE LANCET of Nov. 25th, 1893 (pp. 1326–1336), dealing with gaseous fuel, gas-heating, and gas-cooking appliances, and also to the report of the same commission on the Incandescent System of GAS Lighting, published in THE LANCET of Jan. 5th, 1895 (pp. 51–55), he will see that some of the conclusions there arrived at are in harmony with his own, and he will find also other results of equal interest in connexion with this subject. Mr. Jones, however, has made a useful departure by employing permanganate of potassium for the estimation of impurities over and above carbonic acid, which has no effect upon permanganate. Oddly enough, although the permanganate tests determine different impurities from those of the carbon dioxide tests there is a remarkable agreement between the two sets of experiments. Thus when the carbon dioxide is low the permanganate is only slightly affected; when it is high the permanganate is greatly altered. The question remains as to what the concomitant impurity is. The results are so parallel as to suggest a product of combustion produced uniformly with the carbonic acid. May this not be due to the sulphur ever present, though in small quantity, in coal gas? It should be remarked that weak solutions of permanganate of potassium undergo deterioration in a pure atmosphere, and this raises a doubt as to whether the method is reliable. Still, the results certainly show a remarkable uniformity. We should like to suggest to Mr. Jones that in continuing his interesting experiments he should try the effect of oil lamps. The results would be of interest since oil burns into little else than carbonic acid and water and the question of sulphur would not obtain. The permanganate method adopted by Mr. Jones was that of exposing a solution of permanganate of potassium in a shallow porcelain tray and afterwards estimating by a well-known method the reduction effected in the strength of the permanganate.

THE NOBLE OFFER OF THE MAHARAJAH OF GWALIOR.

IN the House of Commons on the night of July 23rd various questions were asked as to what provision had been made for the care of British wounded in China. Lord George Hamilton in answering said that the Government of India have provided a hospital ship and were preparing to convert three transports into hospital ships. The American hospital ship *Maine* had also been placed at the disposition of Her Majesty's Government, and he begged to express the gratitude of the country to those who had provided and furnished this ship. He was able to inform the House that his Highness the Maharajah of Gwalior had offered to equip fully a hospital ship for China at the expense of 20 lakhs of rupees. This princely offer was made by the Maharajah on behalf of himself, his mother, and his wife, in testimony of their loyalty to the Queen-Empress. This statement was naturally received with loud cheers. At the present exchange 20 lakhs of rupees represents, we suppose, something between £120,000 and £130,000, a gift which is indeed worthy the tradition of Oriental munificence. The century is closing amid stress and trouble of every kind, but never perhaps before have the various items composing the British Empire been so united in their loyalty to the Sovereign. If feudalism has passed away there yet remains the old feeling of faith owed to the head of the body politic, and from the lowliest trooper who is serving his Sovereign to the great native Princes of India there is but the one idea of faithful service.

MEDICAL EXCURSION TO FRENCH MINERAL WATER RESORTS.

OUR Paris correspondent has already announced the forthcoming excursion and we now give some further details. The next Voyage d'Études aux Eaux Minérales Françaises will last from Sept. 2nd to 15th and will be taken up with visits to localities in the south-west of France, including Luchon, Capvern, Bagnères de Bigorre, Argelès, Baréges, Saint Sauveur, Cauterets, Pau, Eaux Bonnes, Eaux Chaudes, Saint Christau, Salies de Béarn, Biarritz, Cambo, Sanatorium d'Hendaye, Dax, and Arcachon. For the similar excursion held in 1899 the locality selected was Central France and Auvergne. The party will consist exclusively of medical men and medical students, who may be of any nationality. The scientific part of the programme has been entrusted to Dr. Landouzy, Professor of Therapeutics in the Paris Faculty, who has arranged for the holding of discussions in different places on the therapeutic applications of mineral water. Luchon will be the starting-point of the expedition, and all the French railways will carry foreign medical men at half the ordinary rates both to Luchon from the place at which they enter France, and also on their homeward journey from Arcachon to the frontier station

where they first arrived. For the trip from Luchon to Arcachon an inclusive charge of 300 francs (£12) will be made to cover all expenses of railway travelling (in special trains), carriage drives, hotels, food, conveyance of luggage, and gratuities. Every information may be obtained from Dr. Carron de la Carrière, 2, Rue Lincoln, Paris, by whom the excursion has been organised. Names of those intending to join the party will be received up to August 15th.

HÆMORRHAGIC EFFUSIONS INTO THE PLEURAL AND PERITONEAL CAVITIES (PLEURO-PERITONITIS) FROM ALCOHOLISM.

INFLAMMATORY effusions occupying simultaneously the pleural and peritoneal cavities are usually due to cancer or tubercle. The following case related by M. Fernet at the meeting of the Société Médicale des Hôpitaux of Paris on June 22nd is remarkable in that neither of these diseases was present, and, further, in that the effusions were hæmorrhagic, a circumstance which is sometimes the result of tuberculous, but usually of cancerous, infection. A man, aged 50 years, entered hospital with intense dyspnœa and mental confusion. He was evidently addicted to alcohol. His illness was of several years' duration. He first had alternating diarrhœa and constipation. Then, two years before, he noticed that his abdomen was enlarging and he felt pains in the right side of the chest. For several months his condition remained stationary, but seven or eight weeks previously to his admission it became suddenly aggravated and he then felt increasing oppression. On examination a large pleural effusion extending nearly to the clavicle was found on the left side. The heart was displaced and pulsated just inside the right nipple. There was a considerable effusion in the abdominal cavity. The lower border of the liver extended below the ribs for a distance of two or three fingers' breadth. There was diarrhœa and the urine contained a trace of albumin. To relieve the dyspnœa puncture was decided upon. Thoracentesis gave issue to dark sero-sanguineous fluid the flow of which was arrested when one and a half litres (42 ounces) had been withdrawn. The patient was relieved and pulmonary resonance and murmur returned in the upper part of the affected side. He was put upon a milk diet. Later abdominal puncture was performed, which gave exit to two litres of fluid similar to that which had been withdrawn from the pleural cavity. Numerous red corpuscles were observed in the fluid. No evidence of cancer or tuberculosis could be found. 550 cubic centimetres of urine containing 16·9 grammes of urea were excreted in the 24 hours. Thoracentesis was performed a second time and one and a quarter litres of fluid were removed which appeared completely to empty the pleural sac. Ten days later, however, it was again full. A third operation gave exit to one and a half litres of similar fluid. The patient became worse: at intervals he had delirium and periods of complete mental cloudiness; the respiration was irregular and of the Cheyne-Stokes type. These symptoms were attributed to uræmia. The renal permeability was tested by the administration of methylene blue. The excretion lasted for five days and was therefore much delayed. He died from uræmia. At the necropsy sero-sanguineous fluid was found in the peritoneal cavity. The intestines were glued together by thin and fragile lymph, indicating recent inflammation. The intestinal peritoneum was cyanosed and blackish in parts, as if ecchymosed. The question arose whether oozing of blood had not taken place and given to the effused fluid its sanguineous character. The liver was enveloped in a whitish fibrous coat at least a millimetre in thickness. The organ was in the condition of atrophic cirrhosis. The spleen had a fibrous covering similar to that of the liver. The capsules of the kidneys were removed with difficulty and the cortex was sclerosed. The left pleural sac contained sanguineous fluid. The right pleura and the pericardium were everywhere adherent. Evidently there had been inflammation of these membranes. Microscopical examination showed renal and pulmonary cirrhosis. M. Fernet attributed all the lesions to alcoholic irritation. Possibly the sanguineous effusions were produced through the medium of the hepatic and renal cirrhosis and the concomitant vascular changes. The fact that these effusions can result from other causes than cancer or tubercle is the important point shown by the case. In the discussion which followed M. Galliard pointed out that in his work, "Les Hémorragies Pleuro-pulmonaires de la Cirrhose," he had shown that hæmorrhagic pleurisy was not rare in cirrhosis of the liver. In THE LANCET of Nov. 11th, 1899, p. 1286, Dr. G. S. Middleton has recorded a case of hæmorrhagic ascites in cirrhosis of the liver (in an alcoholic subject) and pointed that this complication is practically unrecognised. An annotation on "Primary Hæmorrhagic Effusions into the Pleuræ and Peritoneum"[1] and an article on a case of hæmorrhagic ascites published by Dr. Theodore Fisher[2] may also be compared.

PLAGUE IN TURKEY.

ON July 16th Dr. Vouros, sanitary inspector of Beyrout, telegraphed to Constantinople that he had on that day in company with several military and civilian medical men visited four patients employed at a shop in the centre of the city. The extraction of sesame oil was the business carried on at this place. The ages of the patients were from 12 to 25 years. The youngest had been in bed for four days; he had a bubo of the size of an egg in his axilla and a small bubo in Scarpa's triangle; his temperature was 40·5° C. (105° F.); he suffered from vomiting, headache, and mental vacuity. Of the three other patients one had been in bed for four days and the other two for eight days. All three had inguinal buboes, painful on pressure, non-adherent to the skin, and of moderate size; their temperatures were about 38° or 39° C. They complained of headache, but did not vomit. There were no lesions of the skin of the lower limbs on the same side as the buboes. All the patients were Mahamedans from Lebanon. Three had been working in the same shop for several months, but the fourth only for 12 days. A fifth patient, a male, aged 16 years, had been ill and had recovered; he did not exhibit more than an indurated inguinal bubo. All these cases were suspected to be plague and were isolated, their surroundings being at the same time disinfected. Fluid aspirated from the buboes has been examined microscopically by Dr. Férid-Ibrahim, and culture experiments have been made with rabbits, but positive results have not yet been reported. The Conseil Supérieur de Santé has ordered 10 days' quarantine for arrivals from Beyrout. No fresh case of plague has been registered at Smyrna since July 8th.

SULPHONAL HABIT ENDING FATALLY.

Dr. A. E. Taylor and Dr. J. Sailer have published an interesting case in the volume of "Contributions from the William Pepper Laboratory of Clinical Medicine, University of Pennsylvania," just issued, illustrating a somewhat rare condition resulting from the habit of taking sulphonal. The case was that of a woman, aged 52 years, unmarried, and presenting symptoms of hysteria. On inquiry it was discovered that she had been in the habit of taking sulphonal for some time, the dose being 15 grains per diem. She was informed of the evil results likely to follow the continued use of the drug and she discontinued its use for

[1] THE LANCET, Oct. 14th, 1899, p. 1028.
[2] THE LANCET, Jan. 6th, 1900, p. 17.

some weeks. After this she resumed taking the drug and began speedily to exhibit all the symptoms of sulphonal poisoning—viz., mental confusion, marked insomnia, difficulty of speech, and a peculiar sighing dyspnœa. The urine was tinged a deep pink colour (hæmato-porphyrinuria) and a stiffness and paralysis of both legs soon developed. The control of the sphincters was lost. Cutaneous sensibility was not affected. The paralysis spread rapidly upwards and death resulted from cardiac failure. Spectroscopic examination of both urine and blood disclosed the presence of hæmatoporphyrin. At the necropsy the following conditions were revealed. Fatty degeneration was present in the heart, liver, and kidneys. The spleen was filled with a greenish pigment, both free and within the lymphoid corpuscles, the fibrous trabeculæ were greatly increased in size, and the lymphoid follicles were extremely well developed. Excessive pigmentation was found also in the lymphatic glands of the body and in the lungs. No notable morbid changes could be found in the spinal cord or brain. Cases of sulphonal poisoning are rare, and a case like the above in which the necropsy disclosed lesions of a characteristic nature in the various viscera of the body is rarer still and possesses much importance both from a diagnostic and pathological standpoint. It is interesting to note, however, that hæmatoporphyrinuria—an indication of serious alterations taking place in the blood—from the use of sulphonal is nowadays less frequent than in the earlier days of the use of sulphonal when the drug was not always obtained in a state of purity.

ON THE EXCITABILITY OF NERVOUS MATTER.

DR. AUGUSTUS D. WALLER in his presidential address to the Neurological Society published in the spring number of *Brain* dealt with the subject of the excitability of nervous matter with special reference to the retina. The general argument was that "a sigmoid curve expresses the ratio between physical stimulus and physiological effect as well as between physical stimulus and psychological effect," this being a development of the well-known Weber-Fechner law of physiology. The main argument was developed as follows. A nerve separated from its natural termini, isolated from the rest of the organism, gave no sign of life when excited except an electrical change which could be measured and demonstrated with accuracy by suitable apparatus. The electrical response given forth by a living tissue was one of the most general and most delicate signs of life, and a nerve was "an almost ideal sample of living matter upon which to test the comparative effects of all manner of reagents when the galvanometer was made its organ of expression." Living tissue, inasmuch as it *is* living, is also dying tissue, ceaselessly evolving energy and ceaselessly "restoring" it. This double chemical activity, of which living matter is the centre, manifests itself by actual chemical and structural changes when it is sufficiently intense or prolonged, but its weakest and briefest pulsations are manifested by electrical changes. At the moment of exposure of the retina to light and at the moment of cessation of the light-stimulus characteristic electric changes were present, and these curves of electrical variation could be registered on a photographic plate suitably arranged. A latent period occurs at the "making" of the light-stimulus, "a period of hesitation during which a tug-of-war, so to say, is taking place in the retina between two opposite forces or processes, positive and negative, that for a period counterbalance each other in the circuit." A similar, if less pronounced, opposition of forces occurs at the end of illumination, when the forces cease to act. During the continuance of the light-stimulus, however, the positive force rises and remains the stronger, whereas when the stimulus has ceased the negative force rises into prominence gradually. The reactions in an injured or moribund eyeball are different from those of a fresh eyeball excised with the least amount of injury. In regard to the action of colours Dr. Waller, after referring to the theories of Helmholtz and Young on the one hand and Hering on the other, finds that in all cases "different colours give rise to electrical effects in one direction, though of varying magnitude." To quote an instance, the galvanometric deflections gave for red light four units, for blue nine, for green 12, and for yellow 16. It was further proved that, taking two very weak colour-stimuli conjointly—e.g., red and green—the united effect of both stimuli was always greater than either of the separate effects, and not far short of their sum, and that a retina, subsequently to prolonged green or prolonged red stimulation, exhibits equal fatigue to green and to red stimuli. These experiments refer to the frog's retina. Further, the presence and significance of fatigue in nerves was investigated and Dr. Waller concludes that medullated nerves are practically not liable to fatigue, whereas non-medullated nerves, as shown by experiments conducted by Miss Sowton on the olfactory nerve of the pike, appear to suffer readily from exhaustion and fatigue as muscle does. Dr. Waller concludes from the curves obtained as the results of experiments made with gradually increasing stimuli on retina and nerve that a sigmoid curve represents more faithfully than Weber and Fechner's logarithmic curve the relations of stimulus and sensation. The curve in its early stages rises very slowly, then more rapidly, and, finally, it rises more slowly again. And an apt psychological illustration of this is given by language. In the learning of language we know that the first steps cost much and that acquisition is at first very slow. "Then the upward progress becomes more rapid, successive equal increments of energy give successive increasing increments of knowledge; finally, progress slackens, and the last steps towards perfection cost energy far in excess of those taken within the range of mediocrity." Dr. Waller's studies throw an interesting light upon the problem of nervous development.

MASSAGE AS AN OCCUPATION FOR THE BLIND.

THE occupations which can be undertaken by the blind with any hope or prospect of being remunerative and of enabling them to contribute to their own support are unfortunately few in number. Brush-making, mattress-making, basket-making, bookbinding, and piano-tuning, almost complete the list for the less intelligent; tutorial work is occasionally undertaken, though few can hope to be brilliant professors like Penjou the mathematician or like Saunderson of Cambridge. There is, however, a restricted field open to those who have sufficient ability to qualify themselves for the post of organist. We are informed that a small committee of gentlemen and ladies who are interested in the welfare of the blind have resolved at some cost to themselves to make an effort which they trust will receive the favourable support of the profession to introduce a new industry for those who are so unfortunate as to have lost their sight. It is that of massage. It is said that it has been found by actual experience that massage as performed by blind people can be as efficiently practised as by those who see and that their delicacy of touch and intelligent manipulation have been fully appreciated by those placed under their care. It is proposed, if funds will allow, that rooms should be taken in some central situation under the control of a matron who should be in communication with a certain number of thoroughly educated blind masseurs and masseuses. To these rooms physicians and surgeons could send their patients, or if it were preferred, from this centre, as in the case of other nursing establishments, a male or female blind expert could be sent into the country. The blind are clever in making their way about and it is

not apprehended that any difficulty will be experienced in enabling them to reach their destinations, whilst when once they have made themselves familiar with a house their gentleness, quietness, and cheerfulness would be certain to render them satisfactory temporary inmates. Information in regard to the Institute for Massage by the Blind can be obtained from the honorary secretary, Mr. F. Talfourd Chater, Oxford House, Bethnal-green, E.

ANGINA EPIGLOTTIDEA ANTERIOR.

THE *Albany Medical Annals* for July contains an important paper by Dr. C. F. Theisen on this rare affection. "Angina epiglottidea anterior" was the name given by Michel in 1878 to an inflammatory process involving the anterior surface of the epiglottis, as a rule confined to it, and accompanied by more or less œdema, which is the characteristic feature of the affection. The larynx itself may be affected to a certain extent. The disease may be primary, or secondary to acute inflammation of the tonsils, pharynx, or lingual tonsil. The following cases are described in the present paper. Case 1.—A man, aged 36 years, was seen on the second day of an illness which had supervened while he was in good health. Sitting in a chair, with anxious countenance, he complained of a severe sharp sticking pain at the base of the tongue when he attempted to swallow. Attempts to swallow even a few drops of water brought on severe attacks of choking and coughing. There was pain when he moved his tongue and severe headache and anorexia were present. His voice was clear and there was no dyspnœa. The pharynx was not reddened. The anterior surface of the epiglottis was intensely inflamed, of a uniform bright red colour, and œdematous. The larynx was practically normal. The temperature was 101° F., and the pulse was 110. An iced ichthyol spray, one-half per cent. solution, was used every 20 minutes, and an ice pack was applied round the neck. Ice was also frequently taken. On the next day the inflammation had subsided considerably, but there was still dysphagia. On the fifth day he was practically well, though the inflammation did not entirely disappear for several days more. Case 2.—A woman, aged 40 years, in good health, became restless and feverish and had great pain and choking when she attempted to swallow. There was dyspnœa on lying down which compelled her to sit up. The anterior surface of the epiglottis was reddened and so œdematous that the laryngeal entrance was partly closed. The vocal cords were slightly reddened and there was some swelling of the left ary-epiglottic fold. The temperature was 102° and the pulse was 120. Calomel was given and similar treatment to that employed in the previous case was adopted; later in the day, as breathing was still difficult, free scarification was performed which gave some relief. She was much better on the next day and in a week she felt well, although the epiglottis did not become normal for several days more. After the scarification cultures were taken from the epiglottis which showed mixed infection by the staphylococcus albus and pneumococcus. The reason why an œdematous condition of the anterior surface of the epiglottis does not involve the larynx is anatomical. Hayek has shown that the submucosa of the anterior surface is abundant and that the mucosa is not tightly adherent, while on the laryngeal surface the mucous membrane is tightly adherent. But when the œdema is very great it may extend by way of the thin mucous tissue of the pharyngo-epiglottic ligament to the ary-epiglottic folds. As to the causation, angina epiglottidea anterior may result from injury, such as swallowing irritant fluids or substances, or from the inhalation of pungent vapours. It may be part of a general œdema of the fauces resulting from large doses of iodide of potassium. It may occur during infectious diseases, such as measles, erysipelas, septicæmia, &c. Very often it is an acute primary process.

THE HOLIDAYS AND LOCUM-TENENTS.

THE time of holidays is come—for patients. It is not so easy to see how medical practitioners are to secure their much-needed change. With the majority of medical men—perhaps a larger majority than some of us think—taking a holiday is a rare and difficult matter. We remember once to have met a worthy practitioner in an old town of Surrey who had practised for 40 years and had only once had a holiday—and that was when he had typhoid fever! At the present moment the obstacles are unusual. The abolition of the unqualified assistant and the demand for medical men in the naval and military services and abroad are such that a locum-tenent has become an expensive luxury. There seems to us to be only one way out of the difficulty. Medical men must come to terms amongst themselves. They should meet and arrange to give each other holidays; this has its inconveniences, but they must be faced. Such action on their part will moreover have a good effect on the tendency of locum-tenents to over-rate their services. We are not sorry that they are more appreciated than they used to be. Nothing can be more valuable in its way to a medical practitioner wanting a holiday than to know a gentleman of character and ability to leave behind him as a locum-tenent. It doubles the rest of a holiday to be able to leave his patients in the care of such a friend. And they have not always been adequately appreciated. The danger now, however, is the other way—namely, lest they should expect a rate of remuneration more than general practice will bear. The error will be the sooner corrected if medical men in their own neighbourhood and amongst each other agree on a system of mutual help.

LOCAL ANÆSTHESIA AND NARCOSIS.

DR. CARL LUDWIG SCHLEICH contributes to a recent issue of the *Berliner Klinische Wochenschrift* (No. 13, 1900) a long and valuable article embodying the results of his more recent experiences in local infiltration anæsthesia, a subject previously referred to in these columns.[1] He proclaims that it is coming more and more into general use and must in many instances supersede general anæsthesia where the latter may be attended with danger. Infiltration anæsthesia properly conducted is, according to Dr. Schleich, absolutely without danger, owing to the very small amount of the anæsthetic used locally, and it is particularly indicated in all tumours and neoplasms of the skin and subcutaneous tissues—e.g., fibroma, nævus, angioma, lipoma, in most plastic and superficial operations such as tenotomies, excisions of scar-tissue, ganglion, transplantations, and the suturing of fresh and recent wounds and injuries, and for dermoids, chancroids, and sarcomata. The *modus operandi* is to fill the entire skin and subcutaneous tissue at and around the site of the intended operation with the infiltration fluid and to infiltrate the tissue no more than is necessary. In nervous patients the needle-pricks of the hypodermic syringe may be made painless by the application of ethyl-chloride spray. Major amputations may be performed as well as operations on the abdomen (herniotomy and cœliotomy). In injecting the fluid for operation on boils, carbuncles, or abscesses it is necessary to begin the infiltration on the surrounding healthy and non-inflamed tissue. For operation on the fingers or toes the method practised by Oberst—viz., that a ligature should be tightly applied at the base of the digit, after which injection may be made into the

[1] THE LANCET, April 29th, 1899, p. 1171.

subcutaneous tissue—is recommended. The pressure of the blood in this case causes œdema and aids the infiltration to diffuse readily and evenly throughout the finger in about half a minute. Cocaine and its derivatives, tropococaine and nirvanin, are the drugs most employed. Referring to the subject of narcosis or general anæsthesia Schleich recommends that a special solution as follows be used in cases where general anæsthesia is imperative—viz., ethyl chloride one-half to two parts, chloroform four parts, sulphuric ether 12 parts—and he states that he has used this mixture in about 5000 cases without any bad symptoms resulting. Local anæsthesia has been extensively adopted in amputations, resections, and operations on bones (Rubinstein), in gynæcological operations (Abel), and in ophthalmic operations (Wurdemann), as well as for costal resection, urethrotomy, hydrocele, hæmorrhoids, and fistula, &c. Schleich has in 250 cases used the infiltration method in operating on medical men, and with success. As in other papers on this subject, there is less said about the dangers of local anæsthesia than is perhaps advisable. Even when the obvious dangers of sepsis are omitted, since with due care they can be almost eliminated in hospital work provided their presence is appreciated, there yet remain drawbacks to the use of the infiltration method. The average patient does not go through a severe operation even when rendered analgesic—for analgesia and hardly anæsthesia is obtained in Schleich's method—without considerable shock and nerve prostration. There is always the fear that he is going to be hurt, besides the actual sickening pain when the viscera are being handled, which in some cases produces faintness, even collapse. It must be conceded that, valuable as the method is, it should be used as an adjuvant to, rather than as a supplanter of, general anæsthetics.

PLUMBERS' APPRENTICESHIP.

IN London, and, indeed, in the southern counties generally, the system of apprenticeship in the plumbing trade has been gradually dying out, while the plumbers' ranks, as a rule, have to be recruited from a class of men known as plumbers' mates; now the master plumbers, together with the operatives, have at length recognised the importance of this fact. They are of opinion that it is a system alike injurious to the best interests of the London plumbing trade and to the public health. A joint board has therefore just been formed under the influence of the Worshipful Company of Plumbers consisting of certain elected members of the London Society of Associated Master Plumbers together with representatives from the London lodges of the United Operative Plumbers. The aims of the board are to encourage the taking of apprentices under an agreed form of indenture; to exercise a certain control over the apprentice so as to insure his attendance at a duly approved technical school; to occasionally examine him as to the progress made in practical and theoretical knowledge; and finally to register him in order that information respecting his training and abilities may be readily accessible at any future time. It is, indeed, a most welcome sight to see employers and employed united together both for their own and the public good, while so far as the object to be attained is concerned it is one to be commended. The embryo plumber caught in the first blush of early youth is likely to prove like plastic "clay in the hands of the potter." The conditions, however, existing in the plumbing trade, in the South of England more particularly, are not such as to encourage a revival of the apprenticeship system. The scheme suggests a rather expressive Americanism that "there is no good in whopping a dead nigger," and it is to be feared that the process of natural decay in the existing system has passed beyond the reach of stimulants. Unless a course of instruction can be devised, conducted by an organised body upon lines distinctly different to those at present governing apprentices, the difficulties to be overcome are too great to warrant much hope of success. The future development of the joint board will be watched with interest.

HOUSING OF THE WORKING CLASSES.

A CONFERENCE is to be held by the Sanitary Institute on Monday and Tuesday next, July 30th and 31st, for the purpose of considering the problem of the housing of the working-class population in London and other large towns. In connexion with the Conference an exhibition of plans and models is being arranged in the Parkes Museum, and among the drawings that will be exhibited are those prepared for the London County Council, the Corporations of Liverpool, Manchester, Leeds, and Belfast, the Guinness Trust, the Peabody Trust, the Improved Industrial Dwellings Company, and other public bodies. On Monday the Conference will be presided over by Mr. Melvill Beachcroft, L.C.C., and the subject of discussion will be Unhealthy Areas and Displacement of Town Populations. On the second day Sir Sydney Waterlow will preside and the subject for discussion will be Improved Houses for Town Dwellers and Improved Means of Communication. About 400 delegates have been officially appointed by local authorities to attend the Conference, and in the afternoons visits will be paid to the new buildings being erected by the London County Council on the Millbank site, to the Boundary-street area at Bethnal Green, to the dwellings erected by the Improved Industrial Dwellings Company at Bethnal Green, and to the dwellings erected at Richmond, where the delegates will be received and entertained by the Mayor.

ON THE SIMULATION BY HYSTERIA OF OTHER DISEASES.

DR. ERNEST FUERST of Dantzig has published in the *Deutsche Medicinische Wochenschrift*, No. 14, April, 1900, two very interesting cases illustrative of the above, showing not only the degree and extent to which the clinical signs and symptoms of other diseases may be simulated by hysteria, but the practical importance of such cases as regards prognosis and treatment. The first of these was a unique case of œsophageal spasm following the attempt to pass a tube into the stomach. The patient was a woman, aged 36 years, with no hereditary taint, who had suffered for some weeks from gastric disturbances with pains and vomiting of such a character as to point to the presence of gall-stones. There was no icterus, and morphia failed to relieve the symptoms. The vomiting was on one occasion very troublesome and a tube was passed into the stomach. This being done the stomach contents were duly evacuated, but on attempting to withdraw the tube it was felt to be firmly grasped by the œsophagus, which had apparently passed into a condition of spasm. Finally chloroform was administered and when the œsophageal spasm had been sufficiently relaxed the tube was withdrawn. It was then found that the tip of the tube had got folded on itself, probably owing to the spasmodic obstruction being near the cardiac orifice of the stomach, and this combined with the spasm had rendered its withdrawal difficult. The woman was suspected to be suffering from hysteria and was subjected to hypnotic treatment and suggestion, after a brief course of which she was completely cured. The second case was of importance owing to the positive indications which it gave of phthisis. The case was that of a man, aged 29 years, of healthy family. He suffered from pains in the chest, the sputum was slightly blood-stained and there was a febrile elevation of temperature which was not at first suspected to be of hysterical origin. Careful examination of the sputa failed to show the presence of tubercle bacilli, though the

tuberculin test caused an elevation of temperature to 38·5° C. after five milligrammes were administered, and the patient complained of pain over the left side of the chest. The symptoms complained of were, however, peculiar and led to the suspicion of hysteria. Hence an injection of a few drops of distilled water—supposed by the patient to be tuberculin—was given with the result that the same reactions followed, and on another occasion the mere introduction of the hypodermic needle and its withdrawal without making any injection caused a repetition of the symptoms. The case was regarded, therefore, as one of hysteria, and the temperature was attributed to hysterical fever in that it also oscillated in a characteristic and irregular way. With appropriate care and treatment the patient recovered.

ALCOHOL AND THE TROOPS RETURNED FROM THE WAR.

DAY by day it is announced in the press that the victims of war, whether laid low by wounds or by disease, are returning from the front. Some of them are well enough to be sent to their own homes or to convalescent homes almost at once, and we wish to urge upon everyone coming into contact with these returned warriors the plain fact that knowing a man as a friend or the possession of admiration for a man who has done his duty is no reason for treating him to an overplus of alcoholic drinks. We do not say this because we have an objection to alcohol *per se*, but for any man, and more especially for one who has just recovered from a serious illness, to be filled with a selection of alcoholic drinks, and those, too, in many instances, not of the best quality, is conducive neither to his health nor to his chance of success in civil employment. A mixture, as is very possible, of beer, rum, and "whisky-and-soda" is calculated seriously to disturb the progress of convalescence, in addition to the fact that if a man on sick leave is treated to over-indulgence his resulting state of incapacity would not raise him in the eyes of a possible employer. The Army Temperance Association are issuing leaflets upon the same subject. We have treated the matter in a more practical way, but whether it be looked at from the practical or from the intellectual point of view we hope that the pleasure of the return home of those who have done well by their country will not be marred by their being subjected to either the pathological or the legal penalties of over-indulgence in alcoholic drinks.

TABES DORSALIS IN INFANTS.

TABES dorsalis is a rare disease in infants and the cases recorded in literature amount to six in all—viz., three cases published by Remak, one by Strümpell, one by Mendel, and one by Bloch. Dr. L. Dydynsky gives an interesting account of a seventh case[1]—viz., that of a boy, eight years of age, in whom the tabes had its onset at the age of five years and gave rise to bladder troubles. The patient has since then suffered from incontinence of urine and sometimes from retention of urine. He showed Romberg's symptom while standing, the pupils were of the characteristic Argyll-Robertson type, and Westphal's sign (loss of knee-jerk) was pronounced. There were muscular hypotonia and feebleness but no atrophy or manifest incoördination. He had lightning pains and paræsthesia in the lower limbs, as well as patches of hypoæsthesia and hypoalgesia. The personal history of the patient showed a remarkable freedom from any infectious disease and there was not any direct sign of hereditary syphilis. The family history was as follows. The child's father had had syphilis when a young man, aged 20 years, and was at the time of recording of the child's present illness suffering from incipient tabes with characteristic knee symptoms and pupillary conditions. The child's mother had had five miscarriages before the present child was born. Following him were three other children (infants) who so far appear to be well. Dr. Dydynsky insists on the fact that in all the cases observed of infantile tabes and juvenile tabes (Raymond, Homen) syphilis has been noted in the parents, especially the father. Hereditary syphilis is undoubtedly the cause of infantile tabes dorsalis just as it is also the cause of the characteristic cerebral degeneration which may bring about juvenile general paralysis (Thiry, Alzheimer). It is interesting to note that in nearly all the recorded cases of infantile tabes the symptoms began with bladder troubles and troubles of micturition, after which ocular symptoms followed. Troubles of sensibility of the skin followed next in order of time, whereas ataxia and loss of the power of balancing and walking supervened late or did not appear at all. Considering the syphilitic etiology it is a question whether the prevention of both tabes and general paralysis in juveniles might not be effected were appropriate anti-syphilitic treatment adopted in the case of every infant subject to hereditary syphilis. The question opens up one of the most important departments of preventive medicine.

[1] Abstract from the Russian by A. Raichline in Revue Neurologique, May 30th, 1900.

DENTISTS AND THE COMPANIES BILL.

MR. MORTON SMALE, Dean of the Dental Hospital of London, speaking at the conversazione and prize distribution in the Prince's Room, Piccadilly, on Wednesday night, July 18th, adverted to the effect of the Companies Bill now before Parliament on the profession of dentists. He said that almost every clause of the Dentists Act, 1878, began with the words "A person," from which it might be assumed that the intention was to restrict the practice of dentistry to individuals as apart from companies—in other words, that when a person went to consult Mr. Smith he should not be referred to Mr. Jones. This was a professional rule which had led the Royal College of Physicians of London to go so far as to say that even Fellows of the same College should not practise together. Within a few years of the passing of the Act, however, certain persons formed themselves into companies and proceeded to practise dentistry. While the question of remedying this grievance was under consideration the new Companies Bill was brought before the House of Commons and through the instrumentality of some members of the dental and medical professions two clauses were inserted with a view to prohibiting the practice of medicine, surgery, and dentistry by companies. At the moment when they thought they were secure Mr. Ritchie stated in the Grand Committee which was considering the Bill that he thought that it was necessary to drop the clauses because they were not germane to the subject matter of the Bill. Mr. Smale could not imagine that any Act which dealt with the formation of companies should not have reference to this matter, and he failed to see the potency of Mr. Ritchie's remarks. There was no more appropriate place in which to insert clauses for stopping this disreputable practice than this Bill. Everybody in the House of Commons was agreed that the practice was a disreputable one and it was nonsense to postpone the matter indefinitely. It was a monstrous injustice that dentists after going through a five years' curriculum should have to be met by companies carrying on their profession. We thoroughly agree with every word that Mr. Smale said and so does the whole of the medical and dental professions. But unfortunately the clauses in question were excluded on Tuesday night last

when the Bill was considered in the House of Commons as amended by the Standing Committee.

THE Liverpool School of Tropical Medicine has received a communication from the expedition which was despatched last month to America *en route* for Brazil to the effect that, at the suggestion of Surgeon-General Sternberg, medical chief of the United States Army, the expedition had joined for a short period the official Yellow Fever Expedition which the American Government has just despatched to Cuba.

MR. A. MARMADUKE SHEILD has been elected surgeon to St. George's Hospital in the room of Mr. J. Warrington Haward, who retires on completing 20 years' service on the full staff. Mr. H. S. Pendlebury, who has filled the post of Demonstrator of Anatomy and more recently of Surgical Registrar, has been elected assistant surgeon.

WE regret to announce the death of Mr. W. Storer Bennett, F.R.C.S. Eng., L.D.S., dental surgeon and lecturer on dental surgery to the Middlesex Hospital. Mr. Storer Bennett was lately President of the Odontological Society and stood very high in the esteem of the medical profession. He died at the comparatively early age of 48 years.

Pharmacology and Therapeutics.

DORMIOL.

IN an article published in the *Münchener Medicinische Wochenschrift* of April 3rd Dr. Peters of the Luisenhospital in Aix-la-Chapelle gives a very favourable account of a new hypnotic which he has employed in practice for nine months. This substance, which has been named "dormiol" by its discoverer Dr. Fuchs, is a compound of one molecule of chloral with one molecule of amyl hydrate and is an oily colourless fluid having a specific gravity of 1·24 and an odour like that of camphor. It is manufactured by Kalle and Co. of Biebrich, and is sold by them either in the pure state, or in 10 per cent. aqueous solution, or in gelatine capsules. The patients to whom Dr. Peters gave dormiol were almost without exception kept under observation for some time previously, and in order to counteract the influence of suggestion injections of distilled water were given to some of them before the dormiol. These patients were 45 in number, and their morbid conditions were classified under the following heads: nervous system, 20; lungs, 3; heart, 1; intestines, 1; kidneys, 5; liver, 2; peritoneum, 1; genital organs, 2; bones and muscles, 5; blood, 1; chronic poisoning, 2; convalescence after influenza and scarlet fever, 2. They all took dormiol without repugnance, and some said that it tasted like ammonia or ether. It was given either in the form of a 10 per cent. watery solution mixed with milk or in gelatin capsules containing half a gramme (seven and a half grains). No unpleasant after-effects were ever experienced. In seven of the 45 cases no particular effect was produced, but these patients were also found to be unaffected by trional in gramme doses (15 grains), and by amyl hydrate in doses of from four to six grammes. In 84 per cent. of the cases a more or less deep sleep was induced. As with other hypnotics, the effect was for the most part palliative, but in some instances habitual insomnia was permanently benefited. Dormiol was especially serviceable in insomnia due to functional neuroses. It was also tried in cases of organic disease of the brain and spinal cord and was found useful in all but one. A patient suffering from paralysis agitans in whom the smallest mental excitement brought on insomnia was soon sent to sleep by half-gramme doses of dormiol. Half-gramme doses were usually given to commence with, and on an average the hypnotic effect appeared in from half an hour to an hour. The quantity might be increased to one gramme, but it was seldom necessary to give as much as two grammes. In conclusion, Dr. Peters recommended dormiol on the grounds that it was easy to take, that it was harmless in doses of from half a gramme to two grammes, that it was cheaper than other hypnotics, and that it was at least as serviceable as paraldehyde, amyl hydrate, and trional.

IODALBACID.

Iodalbacid is a preparation of albumin containing 10 per cent. of iodine and is recommended as a therapeutical agent on the ground that in the animal organism it appears to be a much more stable compound of iodine than the alkaline iodides, acting less rapidly than the latter but more continuously, and never with the production of the phenomena of iodism. It is a yellow powder, having hardly any taste or smell, and is not readily soluble in water. It is made by L. W. Gans of Frankfort. The dose is from two to five grammes (from 30 to 75 grains) daily, sometimes for several months in succession, taken either in wafers, or baked in macaroons, or in half-gramme tablets. In the *Wiener Medicinische Wochenschrift* of April 7th Dr. Arthur Briess gives a summary of 25 cases of syphilis treated with it in the clinic of Professor Neumann of Vienna. In the greater number of these cases it acted well, and sometimes with comparative rapidity. In some instances, however, it failed, especially in recent syphilis, and other antisyphilitic remedies had to be resorted to. The patients who recovered under iodalbacid mostly suffered from late relapses, exanthemata, papules on the genitals and mouth, periostitis, and gummata. Two patients in whom iodide of potassium produced cardiac troubles, headache, and skin affections, had none of these symptoms when taking iodalbacid. Professor Neumann's patients had from eight to 12 pastilles of iodalbacid daily, with strict injunctions that they were to be taken only after food. Chemical analysis showed that iodine soon appeared in the urine and saliva.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia of the Fellows was held on July 11th, the President, Dr. W. S. CHURCH, being in the chair.

The PRESIDENT informed the Fellows that he had accepted the invitation made to him as President of the College by the Secretary of State for War to become a member of the commission appointed by the Government to inquire into the condition of the sick and wounded in South Africa. In accordance with the by-laws he nominated Dr. F. W. Pavy to act as President during his absence.

On the motion of the PRESIDENT it was decided to send a congratulatory address to the Royal College of Surgeons of England on the occasion of their approaching centenary celebration.

A communication was received from the Secretary of State for War, asking the advice of the College on a proposal for encouraging the investigation of the nature and cause of dysentery affecting armies in the field and its relationship (if any) to enteric fever.

After some discussion the PRESIDENT was requested to express to the Secretary of State the hearty appreciation of the College of the proposal submitted, and to suggest that in their opinion the end in view would best be attained by appointing a small commission of suitably qualified persons to conduct the inquiry.

A communication was read from the Secretary of the Royal College of Surgeons of England reporting certain proceedings of its Council.

Two Reports were received from the Laboratories Committee.

On the motion of the REGISTRAR By-laws 13 and 28, which were amended in consequence of the re-constitution of the University of London, were re-enacted a second time, and By-law 133 which was amended to make it conformable to the conjoint regulations, was re-enacted for the first time.

NOTIFICATION OF MEASLES AND WHOOPING-COUGH.—The Plymouth Town Council has given notice that the order for the notification of measles and whooping-cough will come into operation on Sept. 1st.

THE FIRST INTERNATIONAL CONGRESS ON MEDICAL ETHICS OR DEONTOLOGY, HELD AT PARIS, JULY, 1900.

(FROM OUR SPECIAL CORRESPONDENT.)

IN the large white hall of the cream-coloured Palace of Congresses on Monday, July 23rd, rather more than 200 medical men, coming from all parts of the world, met to inaugurate the first international congress of medical men who have gathered together solely for the purpose of discussing how to organise the profession so as to take an active part in the economic struggles of the day. This is not a scientific congress, unless we qualify political economy as a science, but a meeting of militant medical men who are resolved to maintain the highest ethical standard as the rule of their profession and to defend the economical interests of its members. A considerable number of the delegates who are expected were not present, nor was there any need for all to attend, as it was well known that the proceedings would be of a purely formal character. Nevertheless, it was an encouraging gathering. The few speeches delivered were certainly mild in character; it seemed as if the speakers felt they were treading on new ground and were anxious not to appear prematurely boastful. But there was a thoughtful, earnest tone which is probably quite as likely to produce good results. Dr. Théophile Roussel, senator and author of the admirable law for the protection of abandoned children, was honorary president and opened the proceedings by a few almost inaudible words of encouragement. Dr. Lereboullet, the President of the Congress, then delivered a more lengthy discourse in which he first expressed his thanks to all who in France and abroad had helped to render the Congress not only possible but successful and representative. He pointed out that the time was propitious, for the questions at issue had now reached the domain of practical politics. On all sides it was felt that the profession was overcrowded, that medical men worked more and earned less than formerly, and that their position was attacked from many sides. He denounced quacks, the sale of secret medicines, and unprofessional advertising, as contributing, as well as the great societies that organised contract work, to degrade the profession morally and to lower the incomes medical practitioners might legitimately hope to earn. All these evils could only be met by the organisation of strong medical unions for the purpose of defence and of educating the profession to a knowledge of its economical position. As a secondary task the medical unions might strive to establish some form of mutual insurance against accidents, sickness, and old age. In all these matters at every stage the principles of deontology must be brought to bear, namely, the duty of the medical man to the public, to his patients, and to his professional colleagues. Deontology sprang from the soul. It was difficult to define. It followed the principles of equity, it engendered a sense of refinement, it produced harmony, it obliterated strife, and though the most vague it was the most powerful force they possessed. The medical unions, by bringing the prosperous and the struggling together, helped to engender higher feelings, to efface selfishness, and to create a real professional brotherhood.

Honorary presidents selected from each nationality were then elected, and the general secretary of the Congress, Dr. Jules Glover, gave a short account of the origin and scope of the Congress. He expressed his regret that it would take up too much time to read all the letters of sympathy and approval the organisers of the Congress had received. This correspondence would show how warmly and enthusiastically the Congress had been approved by medical men of all nationalities. Under the Congress hall was the exhibition of social economy and now medical men were also beginning to study social economy as it affected their profession. Dr. Glover went on to show how the various phases of this problem had been intrusted to experienced technicians who had gathered together a great store of facts that bore on the points at issue. There was but little eloquence, but little oratory, in these papers which the Congress would be called upon to discuss, but they were essentially practical and full of information. This opinion will doubtless be endorsed by those who read the subjoined summary of some of these reports which I have been able to make from the proofs. After these few speeches the Congress adjourned to the restaurant of the Congress which faces the Congress hall, where light refreshments were served and the delegates indulged in friendly conversation.

MEDICAL MEN AND FRIENDLY SOCIETIES.

Very shortly after nine on Tuesday morning the real business of the Congress began. The delegates met in the large amphitheatre of the École de Médecine. Dr. LEREBOULLET was in the chair and the discussion was opened on Dr. CUYLITS'S paper. This paper, on the Relations of Medical Men with Benefit Societies, which came first on the list of reports presented to the Congress, was written by Dr. Cuylits of Brussels, and it would be difficult to find in Europe anyone with greater practical experience of the subject. Dr. Cuylits is well known to the readers of THE LANCET as the energetic secretary of the Brussels Medical Union during their memorable strike against the Federation of the Benefit Societies of the Belgian capital. Dr. Cuylits commences by going back to the guilds of the Middle Ages which he describes as a rational attempt to organise labour, but the guilds had now been replaced by trades unions and professional unions. The same spirit of organisation, the necessity of association for mutual help and protection, likewise led to the formation of the vast "mutualities," benefit or friendly societies, to provide pensions and medical attendance in times of sickness, accident, or old age. As in all these cases medical care is necessary the medical officer is the foundation-stone on which such organisations rest. But these societies are philanthropic and not commercial undertakings. Therefore in most countries there are special laws in their favour and they sometimes received subscriptions and donations from benevolent persons. This movement is of the utmost importance because it is spreading so rapidly. Thus in Belgium there were 756 benefit or friendly societies in 1895 and in 1899 they had increased to 2928. In the same time the coöperative societies had augmented from 394 to 1297 and several of them had a medical service for their members. Dr. Cuylits estimates that out of the 6,670,000 persons that constitute the population of Belgium close upon 3,000,000 receive medical aid in some form or other and do not pay the usual medical fees. This state of affairs is not stationary; the evil is rapidly increasing. After alluding to similar conditions prevailing in other countries Dr. Cuylits insists that organisation can only be met by counter organisation. If the medical practitioner is to live in selfish isolation, without coming to a common understanding with his colleagues on matters of common interest, he must inevitably fall a prey to the solid organisations brought to bear against him. On the other hand, by organisation medical men may hope ultimately to abolish the contract system. The members of friendly societies, &c., should receive only financial aid when ill, and with the money thus obtained they would be free to call in and pay for the services of the practitioner whom they prefer. Dr. Cuylits proposes, however, that there should be a fixed minimum charge for each consultation given to members of such benefit societies as apply strictly a wage limit. This fee could vary according to the social standing of the members of the society; it would be notified to all practitioners and none would be allowed to accept less. Dr. Cuylits is uncompromising in his opposition to contract work. Let the subscriber make weekly payments not for medical aid but for money allowances when he is ill and with this money he will be able to secure and pay at a fixed rate per consultation any one of the practitioners who have come to terms with his society.

M. GAYRAL, after Dr. Cuylits had concluded amid warm applause, was the first to speak. He declared that he was in favour of reform, though he represented, not the medical profession, but the great friendly societies. He denounced the presence of wealthy members of such societies. They might remain as honorary members, but should not receive the medical aid intended only for the poor.

Mr. ADOLPHE SMITH (London) then suggested verbal modifications to the motions proposed, as the term *vraie* or "true" friendly societies would not be understood by those who had not followed the discussion. At the request of the secretary of the Congress he gave some details of the abuses prevailing in England, which were greeted with loud applause and not a little laughter. When he insisted that

cheap contract work tended to degrade the profession the Congress enthusiastically and unanimously approved.

Dr. VANDAM, President of the Brussels Medical Union, followed and insisted that the medical officers should have a voice in the management of the friendly societies. He denounced the "blacklegs" of the profession and demanded the creation of a representative body possessing sufficient authority to ostracise those medical men who undersold their brothers in the profession. Such an authority would be greater if it were international.

Dr. LASALLE (Bordeaux) explained how it was sought to establish a minimum fee of one franc per consultation and one and a half francs per visit. This effort had failed through the action of the "blacklegs."

Dr. CUYLITS said he had no fear that his meaning would be misunderstood, for Mr. Smith was not only an eloquent and humorous orator, but one of the ablest correspondents of the medical press and would not therefore fail to make his meaning clear.

After a lengthy and at times a somewhat confused discussion the motions which concluded Dr. Cuylits's report were finally adopted with some slight modification and are as follows:—

No. 1.—All genuine friendly societies, that is to say, societies composed exclusively of workers, are entitled to a minimum tariff which in all other circumstances would be incompatible with the dignity of our profession.

No. 2.—The friendly societies will only be allowed to profit by such tariffs if they undertake to accept and to retain as members only such persons as are in poor circumstances.

No. 3.—These tariffs may differ according to the resources of the friendly societies according to local circumstances.

No. 4.—These tariffs shall be established by mutual arrangement between the friendly societies and the medical societies. These tariffs shall be notified to all practitioners, thus leaving each practitioner free toaccept or reject them.

No. 5.—The system of subscribing (contract work) cannot be authorised under any conditions whatsoever, and the members of the friendly societies are free to select the medical attendant they may prefer.

No. 6.—The administrative committees of friendly societies must comprise a medical man as one of the administrators.

The Congress having unanimously passed these resolutions adjourned for lunch.

INTERNATIONAL RECIPROCITY AMONG MEDICAL MEN.

At the afternoon sitting on Tuesday Dr. SCHWALBE of Berlin opened the discussion on the conditions of practice enjoyed by medical men in other than their own country. Some States, notably Denmark, were very hard on foreign practitioners. Great Britain was, comparatively speaking, very lenient, and so also were Bulgaria, Roumania, and Turkey. —Dr. STOEBER protested against the treatment of French doctors in Alsace and Lorraine, and wanted to see an agreement concluded with Germany similar to that which existed with other countries.—Dr. VANDAM alluded to a Bill before the Belgian Parliament based on the principle of reciprocity. The Belgians would grant the right to practise in Belgium to those foreign medical men who came from countries where Belgian medical men were likewise allowed to practise.

The discussion now drifted from the question of general practice to that of frontier practice. This is a question and a grievance that will not have occurred to the English mind as England has no immediate neighbours, but on the Franco-Belgian frontier it often happens that a Belgian practitioner living in Belgium is nearer to a French farm or hamlet than the nearest French practitioner living on French soil. Therefore, especially in emergencies, it is the Belgian medical man who is called to the French patient. Conventions allowing this so-called frontier practice have been agreed upon by the two countries. It is now said that the Belgian medical men carry out not a "frontier practice" but a "penetrating practice," travelling sometimes 15 miles beyond the frontier and passing the residences of one or more French medical men. The Congress, therefore, adopted the following resolution:—

The Congress resolves that the conventions relating to the practice of medicine on the frontiers be modified, and that the distance which medical men may penetrate beyond the frontiers be precisely defined.

HOSPITAL ABUSE.

The next paper, which was by Dr. PAUL THIÉRY, surgeon on the staff of the Paris hospitals, dealt at great length with the question of hospital abuse. The Medical Union of the Parisian practitioners have discussed this matter extensively and published many pamphlets and articles on the subject. The evil—namely, the use of hospitals by those who can afford to pay fees—is increasing so rapidly in most countries that M. Armand Lefèvre declared in the Municipal Council of Paris that in spite of all efforts to the contrary the time would come when bread and medical aid would be given gratuitously to all who applied, and that the time was not far off when the medical practitioner would be a paid functionary of the State. Dr. Thiéry discusses at length the class of persons who are entitled to frequent hospitals and maintains that workmen protected by legislation rendering their employers liable in case of accident have no right to admission in the hospitals. There is no need of charity in such cases, particularly as the employers are generally insured against such risks. Many cases of abuse are cited, notably that of a jockey who was earning £1000 a year and went to the Hôpital de la Pitié to be treated for a sprain; and a lady was able to pay for her journey from America so as to obtain advice at the same hospital. The cashier of a commercial house earning a salary of £800 went to the Hôtel Dieu, and to-day any number of visitors to the Paris Exhibition profit by the opportunity to obtain gratuitous advice at the Paris hospitals. A young lady came from Russia, was operated upon gratuitously at the Hôpital St. Louis, and then went for her convalescence on a journey to Italy. A celebrated singer wanted the hospital surgeons to come to her own house—she did not like to go to the hospital—and yet she strongly objected to pay any fee whatsoever. All classes and conditions of people seem to think that they have the right to be treated for nothing at the hospitals. Dr. Le Blond had proposed that no one should be admitted whose rent was equal to £40 or more per annum. There are about 50,000 births every year in Paris. Out of these 18,000 take place at the public expense, yet it is scarcely likely that one-third of the mothers in Paris are so poor that they cannot pay for a private medical man. If the well-to-do did not so constantly profit by the public charities the genuine poor would receive greater and more efficient help. Medical practitioners too often are themselves to blame, for they readily give letters of recommendation for treatment at the hospital to patients who should be independent of these charitable institutions. Nor is this grievance met by establishing paying wards and such institutions as the Hôpital Dubois, pompously called the Maison Municipale de Santé, which is practically a cheap medical hotel where wealthy patients only pay a part of what they cost. Dr. Thiéry has sent a circular asking questions to the hospitals of 21 important French towns. The answers received all go to show that no real effort is made to prevent abuse, and the institution of paying patients is very widespread, the charges made varying from 2*s*. to 16*s*. per day, yet the physicians and the surgeons receive no fees from these paying patients. At Havre, however, some attempt is made to ascertain what is the financial position of the patients and at Lyons a certificate of poverty is demanded before a consultation is given at the hospitals. Similar inquiries made in the leading capitals of Europe, and notably in London, show that hospital abuse prevails in all directions and in all countries, and the grievance comprises the paying as well as the other patients. The payment is simply a means of soothing the conscience of the patient; he nevertheless remains a recipient of public charity. For instance, the administration estimates the average cost of the maintenance of patients at the Hôtel Dieu of Paris at three francs 65 centimes per day. But the land on which this hospital stands is worth 75,665,000 francs which if divided by the 563 beds the hospital contains means 134,398 francs per bed. At 4 per cent. interest this is equal to 14 francs 75 centimes per bed per day. Adding the cost of maintenance each bed costs 18 francs 40 centimes per day, and this is not all, for there is the cost of the central administration, so that each patient may be said to cost about 20 francs or 16*s*. per day. Now if a well-to-do patient pays five francs a day he is still taking daily about 15 francs out of the public purse, money which the taxpayer pays so as to help the poor. In response to the efforts of Dr. Porson the Paris Municipal Council recently voted that well-to-do patients should not be admitted in the hospitals and that they might only be received in special buildings when they paid sufficient to defray the entire cost of their maintenance without in any way trespassing on the resources at the disposal of the poor. This resolution has not, however, been sanctioned by the Prefect. In conclusion Dr. Thiéry urges that the clerks or porters at the hospitals, instead of merely taking the names and addresses of patients, should make inquiries as to their means of subsistence. A special inspector attached to the poor relief authorities of each district should then make an

inquiry to verify these statements. The patient on his side should be made to sign an agreement by which he undertakes to pay for his treatment if it should be proved that he has misrepresented his financial position. Should such deception be practised a second time by the same person then there should be a possibility of obtaining a conviction entailing a penalty of a fine and even of imprisonment. Unless under well-defined and altogether exceptional circumstances there should be no more paying patients admitted into the public hospitals. It will be seen that this paper deals with very similar grievances to those described as prevalent in England.

Dr. VACHOT, after Dr. Thiéry had concluded, pleaded in favour of the genteel poor, who he thought were quite as much entitled to hospital treatment as the working classes.

Dr. NOIR (Paris) suggested that the outdoor patients should first be treated at the local dispensaries established by the poor relief administration or Assistance Publique. All such medical relief led to inquiries and charitable persons called at the houses of the people. Such visits would be very disagreeable to persons who were in good circumstances and would materially tend to prevent abuse. In this manner also only the more serious cases would be referred to the hospitals. He further thought that students should begin by this practice among the poor and go to the hospitals at a later stage of their studies.—Dr. VANDAM protested against inquiries made as to the financial position of patients and thought that there was not much hospital abuse in Belgium.—A number of Parisian doctors then followed, warmly debating details of hospital practice in Paris, and the foreign delegates became impatient at the purely local character which the debate was assuming. At last Mr. ADOLPHE SMITH strongly protested that this was an International Congress and that a great part of the conclusions of the report only applied to France. He then narrated some incidents of hospital abuse in England showing the total difference of the state of affairs on the English side of the Channel. This was further explained by a paper written by Colonel Montefiore, which gave many statistics and showed that one-third of the London population received medical aid from charitable and Poor-law institutions. At last the conclusions of Dr. Thiéry's paper were set aside as better suited to a French congress, and the Congress adopted a resolution stating that hospitals should be reserved exclusively for the poor, and that local medical unions should strive to enforce this principle in the manner best suited to their respective local circumstances.

The Congress now adjourned to the big hall of the Hôtel des Sociétés Savantes where "a wine" was offered by the Medical Union of Paris and the neighbourhood. The hall was very elegantly decorated with palm trees and the flags of all nations. The greatest cordiality prevailed and it was generally agreed that a very good day's work had been done.

THE ILLEGAL PRACTICE OF MEDICINE.

The Congress continued its sittings on Wednesday morning when Dr. DESCOURT, Professor of Forensic Medicine at the Paris Faculty of Medicine, read a paper on the Illegal Practice of Medicine. He points out that the economical position of medical practitioners is more and more compromised, not only by the increase in the number of practitioners, by the competition of the hospitals, by the sweating proclivities of medical aid associations, and by the sale of largely advertised patent drugs, but also because a large number of unqualified persons illegally practise medicine. In Paris alone he considers that from 15,000 to 20,000 consultations are given daily by others than qualified practitioners. If this continues medical men will in time be compelled to surrender their independence and become mere employés of the State or of large organisations, companies, &c., whose interest it will be to pay their medical officers as little as possible. The law restricting the illegal practice of medicine is not fully applied. The lay population does not take the matter in hand and medical men are too busy and too poor to risk doubtful and expensive legal proceedings. The remedy lies in the constitution of strong medical unions. Such organisations could undertake legal proceedings and in France have done so successfully on several occasions. These trials may cost each member of a medical union a pound or two in the course of a year but they will save him from illegal competition, and both the moral and material gain is far greater than the cost. Some discussion ensued.

GREAT SUCCESS OF MEDICAL ORGANISATION IN HUNGARY.

In regard to the formation of medical unions a most encouraging report was presented by Dr. ERNEST JENDRASSIK of Budapest. It appears that at first it was proposed to form a chamber of medical men on the model of the Chamber of Barristers which was created in 1874. But it was found that such an organisation would place medical practitioners too much under the control of the Minister of the Interior. By law every medical man would be compelled to join the Chamber; he would be protected by the law, but while many duties would be imposed nothing in the constitution of such chambers indicated that anything effective would be done to deal with the economic condition of medical practitioners. Further, the results acquired in Austria and Germany, where such chambers of medical men exist, was not calculated to encourage the Hungarian practitioners. Therefore they resolved to form a free medical union which was entitled the General Medical Association of Hungary. The rules were adopted at a medical congress held in 1897, and these were shown to the Minister of the Interior and approved by the Government. The object of the association is to unite all the medical practitioners into one great corporation so as to protect their moral, social, and material interests. The association is subdivided into local branches which must consist of at least 20 members, with president, secretary, and treasurer elected for three years. The branches enjoy considerable local autonomy, but must of course conform to the general rules. The central, or, as it is called, the Presidential, Council is the link between the branches. This general medical council consists of a president, two vice-presidents, a general secretary, two assistant secretaries, a treasurer, 10 members selected among the practitioners of Budapest, 20 from the provinces, and the presidents of all the branches. As there are actually 74 branches the presidential council now consists of 112 members and is thus a very representative and influential court of appeal. An annual congress of the entire association is held in September each year at Budapest. The weakest point of this organisation is that it cannot compel by law every medical practitioner to join, but though a chamber may force everyone to subscribe it cannot compel them to obey, and unity of action is more important than the multiplicity of subscriptions.

At first some doubts were expressed as to whether the movement would be successful, but when the first branches became sufficiently numerous for it to be possible to issue a monthly publication recording what had been done the great majority of the medical practitioners of Hungary joined. It is now calculated that no less than four-fifths of the medical men in practice have become members of this widespread organisation. This is a tremendous result, achieved in an incredibly short time, and it seems to indicate that a new principle is more readily adopted in a new country than in the older established nationalities. The General Medical Association of Hungary has already collected statistics setting forth the financial position of the practitioners; it has fixed a tariff of charges for medical examinations for insurance companies; it has drawn up a report on all the laws that affect the practice of medicine and their deficiencies and forwarded the same to the members of the Government. Now the association is engaged in striving to fix a minimum fee for medical consultations which shall also govern the payments made for contract work. Finally, a benefit fund has been created to help medical men who are in distress. Members alone are allowed to subscribe to this fund, but they are not compelled to do so. It is a form of mutual insurance. The fundamental purpose of the association is the defence of the economical interests of the medical practitioners and to abolish that form of competition based on "under-cutting"—namely, taking lower fees. Hence the absolute necessity of establishing a minimum fee and bringing the whole power of the association to bear so as to prevent any practitioner accepting less. The fact that four-fifths of the practitioners of Hungary are members of this association is an example that medical men in all countries should take to heart. It is one of the most encouraging statements that have been made to the Congress. No discussion followed.

The Congress then adjourned.

A DEFINITION OF MEDICAL DEONTOLOGY.

Dr. GRASSET, Professor at the Medical Clinic of the Montpellier University, has a very lengthy paper in which he strives to define and explain what is meant by the term "deontology." This is to be read to-morrow (Thursday), but I send its substance for the consideration of your readers. He protests that the word was not created, as Max Simon says, by Deschambre, but had been previously employed by Bentham in 1747, the British jurisconsult to

whom the National Convention decreed the honorary title of French citizen. Bentham's work was entitled "Deontology or the Science of Duty" and was translated into French by Laroche in 1834. The great Cruveilhier, when writing on the duty of the medical practitioner, said that duty is honour; it is the moral life of man and of society; where it is lax degeneration has set it; where it ceases to exist death soon follows. Deschambre said that for medical dignity to be respected the medical man must first be imbued with the sentiment of self-respect. Max Simon insisted that the preliminary step towards medical reform was to reform the medical man, but Dr. Grasset urges that before blaming medical men for not observing the principles of deontology they must first be certain that they are acquainted with those principles, and at the present time the young practitioner finds no book, code, written rule, or guide in such matters. Now deontology has nothing to do with civil or criminal law. Montesquieu said: "There are means to repress crimes; these are legal penalties; but to correct bad manners there only exist better examples." Jules Simon argued that they did their duty simply because it was their duty, and Max Simon that the abstract idea of duty was alone capable of maintaining the medical practitioner at the height of his mission. "Preserve the cult of honour. In its indefinite character it is superior to the written law, it cannot be reasoned with, it can only be felt, it is a religion." It may be said that deontology is one of the highest phases of the moral law and in no profession is a higher moral standard more necessary than in that of medicine. Therefore, from the very first the medical man will not aim at success in the worldly sense. He will first seek to honour his profession by honouring himself; placing himself beyond the possibility of reproach he will pay every deference to his colleagues and be guided by the sentiment of duty and honour, not by the desire of material gain. If the public are to respect medical men the latter must first respect each other, a fact too often obliterated by feelings of jealousy and the spirit of competition. To judge others leniently and to be severe to one's self and to avoid all backbiting is the surest way to win the public respect for the profession. The Medical Union of the Paris medical men has issued a special circular to its members on this subject. It urges them never to criticise the treatment ordered by a colleague. "Let us remember that any malevolent word discredits not only certain doctors but the entire profession."

Dr. Grasset then proceeds to quote a number of rules drawn up by medical societies of different countries against all sorts of cabals or intrigues having for object to attract clients or to advertise some special remedy. Every form of self-advertisement must be strictly prohibited, as also the giving of commissions to agents, interpreters, couriers, &c., so that they may bring clients to some special establishment where a physician is attached. Monfalcon speaks even of ecclesiastics who bring members of their congregations to certain doctors and are paid for doing so, and then there are touts, matrimonial agencies, but above all hotel servants, who all receive commissions for the patients they send. Dr. Brouardel has mentioned dispensing chemists who received as much as 50 per cent. of the fees paid by the patient they had sent to a particular practitioner. This paying of commissions, though greatly opposed at first, has become very prevalent in France, and though, of course, energetically condemned is thought preferable to advertising. Sometimes the grievance is in the contrary sense and it is the practitioner who receives commissions from the chemist whom he recommends to his patients. This sometimes leads to the prescribing of expensive drugs that are not really needed. Again, there are medical men who receive commissions from the proprietors of hydropathic establishments for sending their patients to these places, and practitioners often receive circulars offering such commissions. Then there are medical men who are shareholders of such establishments and have therefore a direct financial interest in sending their patients where they will help to increase the dividends. There is no law to prevent a medical practitioner purchasing shares of a company that exploits some medical mineral springs. But deontology teaches us that the practitioner should be above suspicion, and therefore it should not be possible to say that he had any financial interest whatsoever in the remedies or methods of treatment he prescribes. In a word, though the medical practitioner has the right to claim payment for his services his first object is not to earn money but to acquit himself with dignity and integrity as a member of the medical profession. His first interest is the interest of the profession; his first care is the honour of the profession; the making of money is altogether a secondary matter; if he thinks money is the first object then let him go into trade or finance.

The next important point in medical deontology is the conduct of medical men towards fellow medical men, and especially when treating the same patient or taking each other's duty. On these matters great differences of opinion prevail among medical men themselves. For instance, in a case of acute illness can a medical man consent to continue a treatment which has been commenced by one of his colleagues? Some reply in the negative and others that the patient should have the right to change his medical adviser if he thinks fit. Dr. Grasset argues that in cases of urgency a practitioner may visit his colleague's patient, but should hand back the case when there is no longer any urgency and not accept any fee. When it is the patient who wants to change his medical adviser the new attendant called in should be in a position to show that he has done nothing whatsoever to bring about such a change, and, above all, that he has not offered to accept lower fees. The patient should be made to give a formal notification to his former medical attendant and the new medical attendant should make it his business to see that his predecessor is paid before he himself accepts any fees. On this point the opinions of a great number of medical authors and of medical societies are quoted which it would take too long to reproduce here.

Then there is the question of nomadic practitioners who go to a town or village once in the month or once a week and of the army or naval surgeons. The former system is only approved for localities where there is no resident practitioner; but with regard to the ethical right of army surgeons to practise among the civil population opinions are very much divided. The expressed opinion of authors and of medical unions is also quoted in regard to the etiquette that should govern the choice of a consultant. So long as the personal and professional standing of the consultant is beyond question the medical attendant must submit to the choice made by the patient. At Bordeaux, however, the opinion prevails that the medical attendant may object if the consultant chosen is not possessed of the special experience the former may judge necessary, and it is suggested that in such a case there should be two consultants, one chosen by the patient and the other by his regular medical attendant. Again, the question is raised—and on this also opinions are divided—whether a medical practitioner should refuse to meet a consultant who is not working in harmony with the local medical union and also whether a consultation with a homœopath should be objected to. It would seem from what is said that there is less objection to act as a consultant when sent for by a homœopath than to send for a homœopath as a consultant. The necessity of punctuality in meeting the consultant, the manner of his reception, the importance of avoiding all criticism or fault-finding in presence of the patient, &c., are dealt with at great length. The opinions of a large number of medical unions are quoted which concur in recognising that in his own house the consulting-room of the consultant is neutral ground and there he may give advice to patients who call on him without inquiring whether they have a regular medical attendant. But at the same time the consultant should not break through this neutrality by persuading his patient to change his regular medical attendant. "Theft for theft, why steal away the confidence a patient has in his doctor?" Also, if the patient is wearing some apparatus the consultant should refuse to remove it unless it be in the presence of the practitioner by whom it was applied. Indeed, in all cases it is preferable that the patient should inform his regular medical attendant that he is going to visit a consultant. After dealing with some other points the paper then proceeds to consider how these ethical principles are to be enforced and at once suggests that there should be a course of lectures on deontology at all the medical schools. Then there should be some book published on the subject and it ought to be placed in the hands of medical students. The *Concours Médical* has offered a prize of £20 for the best pamphlet on the subject and the *Lyon Médical* opened a subscription for a similar purpose. But, after all, such pamphlets would only express the opinions of their authors. The code of ethics should be based on the opinions expressed or the resolutions voted by numerous medical societies or unions. But these associations have all got the defect of being too

local in their conceptions and sentiments; a more general authority is required. Therefore, local societies should federate nationally, and, better still, internationally, and thus create a really representative body which could elect a committee capable of treating such a question in a broad spirit and in a manner applicable to all districts and to all nations.

Paris, July 25th.

THE WAR IN SOUTH AFRICA.

THE news from the seat of war is again unsatisfactory and disappointing. From a military point of view the progress towards any final settlement seems to be very slow, and until General De Wet and his forces have been disposed of or some fresh and decisive movement has taken place on the part of the British it is not likely that things will be otherwise. The history of De Wet's raids and movements and of his successful though chequered career since the capture of Pretoria is remarkable reading. He is a sort of Rob Roy and has shown uncommon skill and ability as a military leader and guerilla chief.

We gather from all the accounts which we have received from South Africa that the cold weather has had a beneficial influence in checking the progress of enteric fever. The reports from medical officers have assumed a much more assured and hopeful tone in regard to it. With the limited railway transport at Lord Roberts's command and its insufficient amount of rolling stock and worn-out and comparatively powerless locomotives, and the long distances that have to be traversed, the difficulties in the way of supplying the army can be readily imagined. It is therefore greatly to be regretted that at this stage of the war we should hear of the frequent interruption of the railway and lines of communication by the enemy's forces.

Now that the South African Commission has not only been definitely constituted but has begun its inquiry at Burlington-gardens under the presidency of Lord Justice Romer we trust that people will be content to set aside for the time being all acrimonious feeling, of which there seems to be a good deal in South Africa, and to patiently await the result. The measures which have been taken to elicit the truth and to guard the witnesses from all injury to themselves in giving their testimony should, we venture to think, satisfy the most fastidious. It is simply ridiculous to suppose that the members of the Commission are not well qualified by their high personal character, attainments, and business qualifications to conduct an inquiry of this kind in an unbiased and thorough spirit. The preliminary inquiry, so far as it has already gone in this country, will have the effect of educating them in the principles of army systems and organisation in matters of transport, supply, and hospital field service generally. It is satisfactory that Mr. Harrison is a member of the Commission, for his intimate acquaintance with railway traffic and organisation, where the matter of transport enters so largely into the question before the Commission, will be very valuable. We may here briefly advert to the letters referring to the subject which appeared in the *Times* of July 23rd. They were all worth reading, but that by Mr. Watson Cheyne struck us, as might have been expected, as especially so. He has had large personal experience in South Africa and took a deep interest in everything connected with the hospital systems in force and he describes what he saw and the arrangements and efforts that were being made and in which he took a prominent part in consultation with the various medical officers concerned. Mr. Watson Cheyne gave evidence before the Commission on Wednesday last.

THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

It is hard to think that we are in July. Really it seems much more than five months since we were getting ready to start in London. Though we are in mid-winter it is so warm in the sun that we are able to carry most of the patients out into the open air for some hours each day. They like it and there is no doubt that it does them good.

Christian De Wet is not broken yet, but surely it cannot be many days before our many divisions which are all round him bring about his downfall from his high pedestal as the one efficient discomforter left and so put an end to the war. There ought to be a big bag soon and there is an impression that Botha will surrender when De Wet is settled and that then the resistance to Lord Roberts will fizzle out quickly. We hear that Lord Kitchener has gone down to have a go at this most sporting of generals. There is, in fact, a widespread feeling manifest in this camp and among those who come into it that the war is all over, and the chief question on everybody's lips is how soon we shall get home. The words "impending dissolution" fairly define the feeling that pervades the hospital. The colonials who came on to our staff in various managerial capacities are all anxious to get away and to return to their permanent work. Our dental surgeon and one of our dressers (Hay) have already gone home. Blathwayt, as I told you, is in the isolation hospital and we have made him the medical officer in charge there. Poor FitzHugh is dead and two of our medical men (Greenfield and Elliot) are still in the wards recovering from enteric fever, so that the number at mess has been somewhat attenuated of late. Breeks, who came out as one of the dressers but who is a qualified medical man, has been promoted to fill the vacancy caused by FitzHugh's death.

I am thankful to say that the epidemic of enteric fever is rapidly diminishing both in the number of its victims and also in the virulence of the disease. This is what we have been hoping for ever since the cold weather set in. The effect upon the work in the various hospitals is immediate and very marked. The report from Bloemfontein is that already the hospitals there are half empty, and certainly the authorities show nothing like the anxiety they did, even two or three weeks ago, to fill up our vacant beds as soon as we notify them as empty. Indeed, we have not taken in a train-load since the sick and wounded from Mafeking arrived a fortnight ago, though small parties of Yeomanry still drop in with great regularity every day—almost, I might say, by every train. In spite of this we have been quite busy with surgery up to the middle of last week. The various hospitals which for some weeks past Surgeon-General Wilson has had ready packed in trucks to be shot up to the stations north of Bloemfontein have not all of them got through even yet. The difficulty is not one of deficient medical resources but of deficiency of transport; for, what with the repeated interruptions inflicted by De Wet upon the railway service, the worn-out condition and the small number of the engines, the delays at the deviations where a bridge has been blown up, and the scarcity of fuel and water, it requires the entire energy of the railway staff to keep the army fed.

My rubber, who came out with me, had to spend a week in hospital lately, and his services were very much missed. He pays from 30 to sometimes as many as 50 visits every day and has been so useful that we have sometimes kept cases in the hospital much longer than we should otherwise have done so that they might benefit from his attentions. Chilblains have been a great nuisance to the sisters recently. I never saw such bad ones as they have had out here, particularly the sisters in the enteric fever huts, for they have to be perpetually wetting and drying their hands.

It is rather late in the day to mention the great loss incurred because friends at home label the parcels they kindly send to South Africa with a full indication of the tempting nature of their contents; the best way is for only a general description to be put on the parcel—e.g., "gifts for the troops," rather than "tobacco," "cigarettes," or "sweets."

I should have spoken of this earlier if I had known how great the loss has been, but I told you before that people "commandeer" in this happy land, and also most people are making collections of any trophies they come across. Mafeking siege stamps are very scarce and are considered cheap at 30 guineas the set of 19, and the siege paper money sells readily at 20 guineas for notes the total face value of which is £2 6s. Talking of Mafeking, we have, as you know, a large number of men here who went through the siege, and it is rather amusing to hear their criticisms of the inflated accounts which reach their ears from outside of the doings of some of their fellow-captives during the siege. Every one of them is loud in praise of General Baden-Powell.

The metal badges of the hospital have arrived and were distributed on Saturday by Lady Chesham to the entire staff. Also the name-boards of the wards and beds have come and

are being stuck up as quickly as possible. Two names which I appropriated for two of my wards are the "Wills" and the "Article Club," because it was owing to some friends of mine that they were endowed—Sir Frederick Wills being personally responsible for the first, while his son, Arthur Wills, prompted the generous efforts of the club which equipped, and therefore named, the second. Mr. Wills was only just starting his good work when we left England, and I am delighted to see that he succeeded in carrying through his project of equipping the whole ward. During the past week there has arrived from the Royal Army Medical Corps Fund in London a welcome present of pipes, tobacco, and clothes for each of the non-commissioned officers and men of our staff. The gift gave them great pleasure, for it showed them that they were not forgotten, and, indeed, I do not think that Her Majesty's forces contain any harder or more devoted workers than the hospital orderlies. Their position is one of considerable danger. I know of one hospital which has lost no less than 30 orderlies from enteric fever out of less than 200, and their work in the words is exacting and continuous. For them there is no such thing as a halt, from the beginning of the war to the end, unless, indeed, they get sick themselves, and they deserve all the kindness and recognition which friends at home can secure for them.

I think I told you some time ago that my wife had kept some of the patients occupied by starting essay competitions. More lately she got one or two of them to try their hands at sketching and some others at wool-work. Both of these pursuits have "caught on" to such an extent that it takes up all of her spare time to keep the hardy warriors supplied with needles and wool and canvas and other necessaries, and it looks most quaint to see them sitting up in bed stitching away for all they are worth. Some of them rush through a pair of slippers in an incredibly short space of time. Others, again, devote their entire attention to the various games that have been sent out from home. Cards, perhaps, form the most popular of these diversions, and when we move the patients, on their reaching convalescence, from the huts to the bell tents and subsequently into the trains for Cape Town, they do not fail to provide themselves with means for whiling away the time, so that there is a perpetual demand for a fresh supply of these smaller articles of diversion to the serious wards.

Deelfontein, July 2nd.

(FROM OUR SPECIAL CORRESPONDENT LATELY AT THE BASE.)

The slack season having set in at Cape Town the usual "military hospital" baiting has recommenced, this time headed by no less a person than the Archbishop of Cape Town, ably seconded by the wife of the Military Secretary to the Governor and the majority of the members of the Good Hope Society, backed up by the *Cape Times*, which paper for some inscrutable reason seems to have delighted from the very commencement of the campaign in throwing dirt at the military medical arrangements. Perhaps some of its staff have been refused admission to the wards when wishing to pass away a leisure hour. They say—or rather I believe that Tennyson does—that half a lie is worse than a whole one, especially if it contains a modicum of truth, but that the *Cape Times* can give credence to the hearsay evidence on which it bases its leader of June 26th gives one the idea that it is only too willing to believe such manifest untruths as it publishes. What can be said for the "charity" exhibited by the head of the Church in South Africa who on the secondhand evidence of a "friend" accuses the medical officers of military hospitals of diverting clothing from the sick, and alleges that blankets provided by the society never reached the wounded, and who further states on the same evidence that only the strongest pressure would induce the "medical men" to supply the necessary comforts? Comment on such statements I leave to abler pens than mine, but I confess to a feeling of utter disgust that any person should be ready to accept on such flimsy evidence such disgraceful allegations against a body of officers who have been working their hardest to overcome difficulties of which a person in the archbishop's position can have no knowledge. I pass over the remarks of the Rev. J. J. McClure, as of course he followed in his superior officer's footsteps, and any remarks which he might make regarding the dieting of patients or their treatment by the medical authorities must be put down to ignorance of the matter in question, but still it shows the necessity of measures being taken by the proper authorities to keep meddling interlopers outside the precincts of military hospitals. The medical officers in charge of our hospitals are quite capable of doing their duty without interference from the outside by irresponsible persons, and if they do not there are means of supervising them without any assistance in the shape of "visiting ladies," whose presence, in the capacity for which they are delegated, is an insult to the medical authorities. It is a curious coincidence that this hysterical agitation should have taken place in Cape Town synchronously with the letters to the *Times* written by Mr. Burdett-Coutts, who was staying in Cape Town prior to embarking for England. To put an end once and for all to this constant interference by these (I do not doubt well-meaning) people I would suggest a committee of inquiry to investigate these alleged atrocities who should take the evidence of the men themselves, who, I must say, are remarkably silent regarding them.

I am happy to say, turning to a more genial subject, that enteric fever is diminishing in Bloemfontein and that the general health of the troops is undoubtedly improving, though, of course, every week sees a great number of invalids homeward bound. Still, on the whole there is a distinct improvement and the pressure on the hospitals is lessening.

Bloemfontein, July 1st.

THE ACTION OF THE SMALL-BORE BULLET AND SHELL FRAGMENTS AT THE SIEGE OF MAFEKING.

To the Editors of THE LANCET.

SIRS,—The Mauser bullets as generally used by the Boers at the siege of Mafeking are of small calibre, low trajectory, high velocity, light in weight, and covered with a nickel casing. They do not cause any great amount of bruising in and around the wound and they are not so liable to smash a bone as are bullets of large calibre and slower velocity. In most cases the bone is merely perforated or grooved, and the missile passes through the body or limb and rarely lodges. It appears that the small quantity of bone carried on by the Mauser bullet after passing through a bone is so pulverised by the high velocity of the projectile that the particles are lost in the tissues surrounding the exit from the bone, and do not in any way retard healing of the parts, as spicules of bone formerly did when a bullet of large calibre was used; both the wound of entry and the wound of exit are small. At a range of about 1200 yards and upwards the Mauser bullet appears to lose its great velocity, as the wound of exit somewhat enlarges. This is caused by the bullet having a tendency to become deflected out of a straight line by meeting with resistance when the range is great, but as a general rule it passes through the body and rarely lodges. The fatality following the wounds made by the Mauser bullet is very low, especially in relation to the limbs, even when joints are implicated. I observed one patient who was shot through both frontal lobes; he was again on duty in a few weeks. Wounds through the lungs proved fatal, also no cases recovered where either the large or small intestines were perforated. Flesh wounds healed very quickly and without suppuration. On one or two occasions the nickel casing surrounding the ordinary bullets used stripped in the wound without any apparent contact with bone; when this occurred the wounds healed slowly and suppurated considerably. The stripping was probably caused by some defect in the manufacture of the bullet or by the enemy having tampered with the nickel-coating before firing.

Shell wounds.—Shell wounds of all descriptions healed with great difficulty, and the suppuration in most cases was profuse. This is accounted for in consequence of the great amount of tearing and contusion which the tissues encounter, by the large surface exposed, by fragments of clothing being carried into the wound, by pieces of shell, and by the general dirty condition of the projectiles. The shock to the system is in all cases very great, and was often the cause of death, as hæmorrhage is usually slight in all cases of wounds caused by shell fragments. From personal observation and practice I found that shell wounds treated by copious antiseptic irrigation, free and continuous drainage by ordinary indiarubber tubes, and apposition of the torn tissues by deep and superficial sutures, gave the most satisfactory results.

I am, Sirs, yours faithfully,

F. A. HOLMDEN, M.B. Edin.,
Medical Officer, Her Majesty's Service, British Bechuanaland Protectorate.

June 15th, 1900.

CENTENARY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE PROGRAMME OF THE FESTIVAL.

THE proceedings in connexion with the Centenary Festival of the Royal College of Surgeons of England began on Wednesday morning, July 25th. From 11 until 1 in the unrivalled museum of the College Professor C. STEWART gave demonstrations to the Fellows, Members, and guests of the College. During the same hours Dr. T. G. BRODIE, director of the laboratories of the Conjoint Board, gave lantern demonstrations at the Examination Hall, Victoria Embankment, in illustration of the work done under his surpervision.

MEETING OF THE COUNCIL.

The August Council meeting of the College was held in the afternoon, the President, Sir WILLIAM MAC CORMAC, Bart., K.C.V.O., being in the chair.

Dr. FREDERIC SHEPHARD DENNIS was introduced and after signing the by-laws and making the required declaration he was admitted a Fellow of the College.

The SECRETARY reported the death on July 19th of Mr. Storer Bennett, elected on July 12th a member of the Board of Examiners in Dental Surgery.

The Council passed a vote of condolence with his family.

The PRESIDENT stated that the vacancy in the Board so occasioned would be filled up at the quarterly Council meeting in October.

The PRESIDENT reported that the deputation appointed by the Council had attended at Marlborough House on July 24th and had conferred the Diploma of Honorary Fellow on H.R.H. the Prince of Wales.

The Council proceeded to elect to the Honorary Fellowship 35 surgeons whose names we have already given.

A letter was read from Sir Henry E. Roscoe, Vice-Chancellor of the University of London, requesting the Council to appoint two persons to represent the College on the Senate under Section 12 of the Statutes. The Council appointed Mr. H. G. Howse and Mr. A. Pearce Gould.

Professor PACHOUTINE, President of the Imperial Military Academy of Medicine of St. Petersburg, presented to the Council an address of congratulation on the centenary of the College. Addresses of congratulation were also received from Professor Sklifossovsky on behalf of the Imperial Clinical Institute of the Grand Duchess Helena Pavlovna, from the Royal College of Physicians of London, and from the Royal Institute of Public Health.

THE CONVERSAZIONE.

On the evening of Wednesday there was a well-attended conversazione at the College, when the English surgical and scientific world was thoroughly well represented, although the tropical heat no doubt accounted for some regrettable absences.

On the morning of Thursday Professor C. STEWART and Dr. T. G. BRODIE continued their work of demonstrating, and at 2.30 P.M.

THE CENTENARY MEETING

was held in the theatre lately used by the University of London at Burlington-gardens. Sir WILLIAM MAC CORMAC then delivered the following address of welcome.

AN ADDRESS OF WELCOME BY SIR WILLIAM MAC CORMAC, BART., K.C.V.O., &c. (PRESIDENT).

MY LORDS AND GENTLEMEN,—One hundred years have passed since the charter granted by King George III. incorporated the surgeons of England into a Royal College, whereby the art and science of surgery might be the better cultivated and the commonweal of the people of this kingdom benefited. We meet to-day in order to celebrate the centenary of our incorporation, and the occasion compels us to reflect how far the College has fulfilled its high mission and merited the public consideration and confidence it enjoys and, as we believe, deserves to enjoy through unselfish service to the State.

My first and most pleasant duty is to welcome our illustrious guests who have come from many and distant countries to do honour to our College. Amongst them are great surgeons from almost all the nations, men who not only hold the highest professional position in their respective countries, but whose public record has made their name familiar to us all, while many of them are dear personal friends. We have guests, too, our own countrymen, whom we delight to honour; dignitaries of the Church and of the Law and heads of our ancient seats of learning. Although I cannot enumerate all, I can and do extend to each and every one the most cordial welcome and would wish to express our grateful appreciation of their presence amongst us.

An occasion like this possesses historic interest. We contrast our present position with that of our predecessors, and rightly congratulate ourselves on our greater knowledge and opportunities, on the facilities we enjoy for investigating the mystery of disease and for its more effective treatment. The comparison enables us to realise, as only such a comparison can, the extent of our gains and our increased opportunities for doing good. It leads us at the same time to recognise as we ought how large a debt we owe to the workers who have preceded us for so many of those happy results which are now matters of daily accomplishment.

The progress of surgery has been greater during the present century, more especially in the latter portion of it, than in all the preceding centuries combined, and it is of especial interest to us to note that this period of rapid advancement exactly corresponds with the life-history of our College, whose centenary we are assembled to commemorate. If we look back—and it is well to look back sometimes—we find in the labours of the old masters of surgery much to enlighten, to widen, and to confirm our views. A knowledge of the history of our art and science tends to make us juster judges both of our own work and of that of others. When we search the history of the development of scientific truth we learn that no new fact or achievement ever stands by itself, no new discovery ever leaps forth in perfect panoply as did Minerva, from the brow of Jove. Absolute originality does not exist, and a new discovery is largely the product of what has gone before. "We may be confident that each forward step is not ordered by one individual alone, but is also the outcome in a large measure of the labours of others. The history of scientific effort tells us that the past is not something to look back upon with regret, something lost, never to be recalled, but rather as an abiding influence helping us to accomplish yet greater successes."[1] Again and again we may read in the words of some half-forgotten worthy the outlines of an idea which has shone forth in later days as an acknowledged truth.

We see numerous instances of this in the history of surgery. Some fellow worker in years long past has discovered a new fact or indicated the path leading to a fresh truth. It is forgotten, and a century later something nearly the same, or mayhap a little better, is discovered afresh. The psychological moment has arrived, and the discoverer reaps the reward not only of his own labours but of those of his predecessors as well. The countless trials and experiments which ended in the general use of ether and chloroform in surgery—that trebly blessed discovery of a sure relief from pain—were guided by the experience of previous trials, half successful, half failures. The patient labour of our distinguished Fellow, Lord Lister, now President of the Royal Society, has been rewarded by a success to which all the world does homage, and which will crown his head with imperishable laurels. Yet none will be readier than Lord Lister to acknowledge how much the antiseptic methods of wound treatment owe to the researches and discoveries of Pasteur.

If we examine the old books we may find again and again something very near to what is the accepted doctrine of the present time.[2] History, it is said, repeats itself, and so very certainly does surgery. The difficulty of discovering anything really new is as great in surgery as in other branches of knowledge. Hippocrates (460 B.C.), the father of medicine, classified injuries of the skull in much the same way as that adopted in our modern text-books. He spoke of contusions of the cranium without fracture or depression, of simple fractures, depressed fractures, indented fractures involving the outer table alone, and fractures at a distance from the seat of injury which we now style fractures by

[1] Presidential Address, British Association, Dover, 1899, by Sir Michael Foster, K.C.B.

[2] For many of the details which follow I am indebted to an interesting history of surgery by Dr. Billings, which is to be found in the "System of Surgery," by Dr. Dennis, F.R.C.S., of New York.

contre-coup, a classification which leaves but a small margin for improvement. Many of the surgical instruments found in Pompeii are precisely similar in principle, if not quite equal in workmanship, to those now in use, and Pompeii was destroyed 1800 years ago (A.D. 79). Heliodorus, who lived at the beginning of the second century A.D., in the time of the Emperor Trajan, was a surgeon of much originality and appears to have been familiar with some of our modern methods and discoveries. He knew, for instance, of the ligature of arteries, of the radical cure of hernia by extirpation of the sac, and of the excision of a rebellious stricture of the urethra. Oribasius, who flourished in the middle of the fourth century A.D., was the friend and physician of the Emperor Julian. He has preserved for us the work of Antyllus, whose treatment of aneurysm by ligature of the vessel above and below the sac, with subsequent incision and evacuation of its contents, has of late years been revived with success, and is still considered by many of our surgeons as the best method of treatment in certain cases. One might cite other examples of old methods consciously or unconsciously revived, but these may perhaps suffice. The modern specialist finds his prototype in very ancient times and what we are apt to regard as a recent development is in reality a survival. Herodotus tells us that in Egypt there were as many branches of the profession as there are parts of the human body.[3]

In Europe, until the rise of the Italian Universities, surgery was mainly in the hands of peripatetic charlatans who cut for stone and operated on hernia. They travelled from town to town, kept their methods secret, and handed them down as family property to their descendants. The Hippocratic oath restricted the performance of lithotomy to those who had specially devoted their whole energies to the cultivation of this operation, and may partly serve to explain this remarkable survival. Some of these "cutters" were skilful men, but all were of necessity very ignorant. A very famous "cutter," whose name we do not know, died in Genoa in 1510, and Senerega, the Genoese historian, tells us that his method was to introduce an iron rod along the urethra into the bladder until it touched the stone, which he then extracted through a perineal wound. It has been suggested that this Genoese taught his method to John of Cremona who is credited with the invention of the grooved staff. One of the most celebrated "cutters" was Pierre Franco who was born in Provence about 1500 A.D. He used a staff and cut on the gripe as well and employed instruments for the purpose of crushing large stones. He was a man of determination and resource for he relates a case of a boy in whom, having failed to remove a stone by way of the perineum, he successfully performed the supra-pubic operation. The stone was of the size of a hen's egg and the patient subsequently made a good recovery. Colot was appointed lithotomist to the Hôtel Dieu of Paris in 1556. He had learnt what is known as the "Marian operation" from an itinerant quack, and he practised the method with, it is said, much success. The office and its secret descended to his son and to his grandson. In the great metropolitan hospitals—in St. Bartholomew's and St. Thomas's, for instance—persons were at one time specially appointed for the purpose of cutting for stone. John Bamber, who lived during the reigns of William III., Queen Anne, George I., and George II., was the last of the special lithotomists at St. Bartholomew's. He resigned his office in 1730, and his duties were transferred to the surgeons of the hospital, who were specially paid a small stipend each year as lithotomists until 1868. Bamber's portrait, by Verelst, may be seen at Hatfield House, and Lord Salisbury inherits some portion of his property through an heiress of this line who married a Marquis of Salisbury. At St. Thomas's Hospital certain of the surgeons were specially appointed to cut for stone, but before the year 1730 there appears to have been a special "surgeon for the stone," and the first of these was James Molins, who held a similar office at St. Bartholomew's. There is, indeed, no end to the matters of interest in the history of our art.

The great French surgeon Guy de Chauliac, who was born about 1500 A.D., studied at the three most famous centres of learning of that time—Bologna for anatomy, Paris for its surgery, and Montpelier for medicine. He travelled much, but finally settled at Avignon, where he became physician in succession to Pope Clement VI., and afterwards to Pope Innocent and Pope Urban. It was in Avignon he wrote his "Great Surgery," and in a special chapter of this work he records opinions which have an application even in the circumstances of our own times. "Formerly," he says, "all medical writers were both physicians and surgeons—that is to say, well-educated men; but since then surgery has become a separate branch and fallen into the hands of mechanics." It is interesting to find from Guy that there were in his day exponents of that modern foolishness called "Christian Science." These Guy describes as "consisting of women and many fools." They refer the sick of all diseases to the saints, saying: "Le Seigneur me l'a donné, ainsi qu'il Lui a plu. Le Seigneur me l'ostera quand il Lui plaira, le nom du Seigneur soit bénit. Amen." As a striking instance of my thesis I may take the great French military surgeon Ambroise Paré. We know his title to fame in substituting the ligature of arteries for the use of the hot iron in the arrest of hæmorrhage. We know also the story of how he forbade the barbarous practice of pouring boiling oil into gunshot wounds, due to the then prevailing belief that these wounds were poisoned, a belief revived with almost every war, even the latest one in South Africa. Paré had been apprenticed to a provincial barber at the age of nine years. Soon afterwards he came to Paris, attended lectures at the Faculty of Medicine, and gained admission to the Hôtel Dieu. He lived there as a dresser for three years, "seeing and knowing a great variety of diseases constantly being brought there." He was only 19 when he accompanied the king, François I., into Provence to meet the army of Charles V. He was attached to the Courts of four kings of France and, although a Huguenot, was spared at the massacre of St. Bartholomew by the direct intervention of Charles IX. It is interesting to learn that Dionis, more than 100 years after Paré's time, was urging at the Hôtel Dieu the adoption of arterial ligature in place of the caustic even then in vogue. Dionis, too, although he advised the Marian operation for stone, considered that the risks of the suprapubic method had been over-estimated, an opinion revived and insisted on by Sir Henry Thompson in our own time. We all remember J. L. Petit (1674–1750) who invented the tourniquet known by his name in the early part of the last century, and Anel who tied the brachial artery for traumatic aneurysm at the bend of the elbow, upon which procedure a claim was based for priority over Hunter, though Hunter's operation is wholly distinct in the principle involved. Towards the end of the eighteenth century, Desault, who nearly lost his life in the Revolution, was the leading French surgeon. He was accused of poisoning the wounds of some of his revolutionary patients in the Hôtel Dieu, and to be accused was in those times almost the same thing as being condemned. Desault, whose fame has been eclipsed by the brilliance of his pupil Bichat, was the first surgeon to teach surgical anatomy after the modern manner, although the great French hospital where he practised was described at that time as "the oldest, largest, richest, and worst hospital in Europe." I need not refer to more recent and greatly honoured names—Dupuytren, Velpeau, Nélaton, and many others.

In Germany, even so recently as 100 years ago, surgery was at a low ebb. George Fischer[4] tells us that quacks of all kinds, "cutters" for stone and hernia, cataract operators, and bone-setters, flourished in the land. The public executioner, whose business it was to fracture bones and dislocate joints on the rack, was supposed thereby to have acquired a knowledge of disorders of these parts and was consulted freely about them—so much so that Frederick the Great in 1744 published a decree limiting the powers of these men, and while permitting them to treat fractures, wounds, and ulcers forbade them to practise medicine. Hildanus (1560–1634), who lived in Germany at the end of the sixteenth century and beginning of the seventeenth century, has been called the father of German surgery. He was a voluminous writer, a bold operator, and his "Opera Omnia" was a work of reference for many years. Heister (1683–1758), a surgeon of much note in the eighteenth century, wrote a "General

[3] "The medical profession," he says, "is distributed among them [the Egyptians] in this wise: each physician is for a single disease, and not for more. The whole land swarms with physicians: some are appointed for the eye, some for the head, some for the teeth, others for the region of the belly, others again for unseen (internal) diseases.'—Herodotus, ii., 84.

[4] Chirurgie vor 100 Jahren, Historische Studien.

Surgery," which enjoyed much repute and was translated into English. Bilguer (1720–1796), a surgeon-general in the German army, was noted for opposing the indiscriminate amputation of limbs then in vogue for gunshot fracture of the extremities which his predecessor Schmucker had warmly advocated and practised to an inordinate extent. Towards the end of the eighteenth century Von Siebold (1736–1807), a famous surgeon who enjoyed great repute as a clinical teacher and operator, taught anatomy at Würzburg, and about the same time Richter (1742–1812) was professor of surgery at Göttingen. Richter had travelled much, was familiar with the work done in England and France, and was the best writer and teacher of his day. He was the first to place surgery in Germany on a truly scientific basis. Of those German surgeons whose names still fill our ears with their fame and whose loss we have recently deplored—Stromeyer, Langenbeck, Billroth, Volkmann, Thiersch, Nussbaum, and others—I could only repeat what all of you know as well as or better than I.

The first English surgeon of whom we possess any definite knowledge and whose writings are still in existence is John of Arderne; he was born in 1307. He must have been an accurate and close observer, to judge by the graphic description which he furnishes of cancer of the rectum. He says: "It breeds within the fundament with great hardness but with little pain. After a time it is ulcerat, oftentimes all the circumference, and the excrement goeth out continuallie." He gives a true and telling description of how the condition is to be diagnosed, and of the progress and termination of the disease.

It is noteworthy how many of the older surgeons who attained eminence spent part of their career in the army or Navy. William Clowes (1540–1604), who was surgeon to St. Bartholomew's, had been a surgeon in the navy, and wrote "A proved Practice for all Young Chirurgeons concerning Burnings with Gunpowder and Wounds made with Gunshot," and he refers to Ambroise Paré in terms of admiration. The greatest English surgeon of the seventeenth century was Richard Wiseman (1622–1676). He served in the Dutch Navy till 1644, and then entered the army of Charles I. Afterwards he spent three or four years in the Spanish navy and on the restoration joined the forces of Charles II., by whom he was appointed one of his surgeons. He published many treatises, which exercised a considerable influence on English surgery but were little known abroad. William Cheselden (1688–1752) was a surgeon of great renown in England in the early part of the eighteenth century. He was a surgeon and lecturer at St. Thomas's Hospital. In 1723 he published a treatise on the high operation for stone, but he soon abandoned this for the lateral method which he so much perfected and improved that the operation remains at the present time much as he had left it. Percivall Pott (1714–1788) was the famous English surgeon of the middle portion of the last century. He was surgeon to St. Bartholomew's Hospital, and made many and most important contributions to surgery, especially on hernia and on injuries to the head. His name remains attached to many surgical disorders. Of John Hunter (1728–1793) no detailed mention is required here. His memory and his methods continue a living influence amongst us. He made our surgery a science, and has given to us in our museum an imperishable memorial of his industry. In it are illustrated those marvellous powers of observation which had never before been equalled, and will never in all probability be surpassed. So long as surgery continues Hunter's influence must be felt. It is witnessed in the creation of so many distinguished disciples imbued with his principles and able to expound his doctrines. He embodies and represents the glory of our science, our College, and our country.

The historical *résumé* I have attempted would not be complete without some account of the connexion existing between the Surgeons and the City of London which appears to have continued quite without interruption since the middle of the fourteenth century until the foundation of the Surgeons' Company in 1745.[5] There are many entries in the City records of the admission by the Lord Mayor of Surgeons and Master Surgeons to practice in the City of London, and the licence thus granted exacted a promise "that they should well and truly serve the people in their cures and report to the Lord Mayor and Aldermen any Surgeon neglecting his patients." In 1416 the Craft of Barbers practising Surgery petitioned the Lord Mayor and Aldermen "to provide a sure remedy against unskilful persons who indiscreetly pretend to be wiser than the Masters of Surgery, and who expose the sick to the greatest danger of death or maim by their presumption." The City took immediate and, as we learn, successful action on this petition. The City recognised the distinction between Barbers and Surgeons, for they appointed "Masters of surgery" to control those practising surgery only, and other masters were annually selected to supervise those practising barbery. Early in the fifteenth century the surgeons appear as a distinct body, and in 1423 a College of Physicians and Surgeons, which had been founded chiefly through the influence of John Morstede, a surgeon who accompanied Henry V. to Agincourt, was formally sanctioned by the Lord Mayor, and powers granted to it to examine and control persons practising medicine and surgery in the City of London.

The Livery Company of Barber-Surgeons was founded in 1540 and its Hall in Monkwell-street is still standing, as it escaped destruction in the Great Fire of London. The famous picture by Hans Holbein of Henry VIII. delivering the charter of the company to the assembled Barber-Surgeons is still there, where until recently one might see the old theatre, where lessons in anatomy were read upon the bodies of executed malefactors. Thomas Vicary (149(?)–1561), sergeant-surgeon to the King, the first Master of this Company, was a wise and honest gentleman. He held a unique position at St. Bartholomew's, and there is in Holbein's picture at the Barber-Surgeons' Hall a characteristic portrait of him. Vicary was succeeded by Thomas Gale (1507–1587), who had served with the army of Henry VIII. in France in 1544 and under Philip II. of Spain in 1577. In his "Institutions of Chirurgeons" there is an account of wounds made by gunshot. He opposes the view that they are poisoned, and gives cases to prove that bullets may be left for long in the body without danger. The Barber-Surgeons appear to have borne their due share in the city pageants. At one pageant given at the Restoration the Lord Mayor and Aldermen appointed that the Company should provide "twelve of the most grave and comlyest personages; appareled with velvet coats, sleeves of the same, and chaynes of gold, to attend the Lord Mayor on horseback." Mr. Edward Arris, an alderman and barber surgeon, had a great desire to increase the knowledge of chirurgery, and to this intent bequeathed to the Company a sum to found lectures, in 1645, on anatomy, on condition that a "humane" body should once in every year be publicly dissected. The Gale Lecture was founded by John Gale a little later, in 1655, and Havers, well known for his description of the canals in bone, since called Haversian, was appointed the first reader. The Arris and Gale Lectures are still annually delivered in this College, for when the Surgeons finally separated from the Barbers in 1745 they carried nothing with them but the Arris and Gale bequests. The hall, library, and plate remained the property of the Barbers, and the new Company of Surgeons had to make a fresh start in the world.

The Act of Parliament separating the Surgeons from the Barbers became law in 1745, and a corporation was established consisting of a "Master, Governors, and Commonalty of the Art and Science of Surgery in London." John Ranby, one of the prime movers in effecting the change, became the first Master. He was serjeant-surgeon to George II., and accompanied that monarch to the battle of Dettingen in 1743. The other active mover was Cheselden, surgeon to Queen Charlotte's, to Chelsea, and to St. Thomas's hospitals. The first meeting of the new Company was held in the Stationers' Hall on July 1st, 1745. Mr. Ranby, as Master, occupied the chair, and Mr. Cheselden and Mr. Sandford were his wardens. Ten examiners were appointed to conduct the examinations of those seeking the diploma of the newly constituted company, and this number is continued in the present Court of Examiners. Part of their duty was to examine surgeons for His Majesty's army and navy, and the examination of surgeons for those services, which had been instituted in the reign of Henry VIII., was continued for a long time by the Court of Examiners until other arrangements were made at a comparatively recent date. It was for this examination, I may note in passing, that Oliver Goldsmith presented himself in order to qualify as a naval surgeon's mate on Dec. 21st, 1758. He was unsuccessful and it was well; perhaps, since he could scarcely have written "The Vicar of

[5] South's Memorials of the Craft of Surgery.

Wakefield" in the cockpit of a man-of-war. In "Roderick Random" we possess a graphic and probably fairly correct description of one of these examinations, derived, doubtless, from Smollett's personal experience, as he obtained the Company's diploma for the post of surgeon in His Majesty's navy.

The Surgeons established themselves in the Old Bailey and there they built a theatre. In 1753 Percivall Pott and John Hunter were chosen as the first Masters in Anatomy, and no more brilliant choice could have been made. It is recorded that immediately after this election the Court proceeded to discuss how they should dispose of the bodies of the three persons who were to be executed a few days afterwards for "murther" and then sent to the College theatre to be dissected. Amongst the bodies brought in this way was that of Lord Ferrers, executed in 1760 for killing his steward. It was not, however, dissected, but was buried in Old St. Pancras churchyard at the intercession of Lady Huntingdon. On July 7th, 1796, Henry Cline the elder was elected a member of the Court, but, as it subsequently turned out, the meeting at which this occurred was irregular and its proceedings were illegal, a properly constituted quorum not being present. Although only a technical illegality had taken place this incident led to the final extinction of the Company of Surgeons, for a Bill shortly afterwards introduced into Parliament to legalise the proceedings was thrown out and the Company was thereupon dissolved. The Bill had passed the House of Commons but was rejected in the House of Lords, mainly through the influence of Lord Thurlow, who was bitterly opposed to Mr. Gunning, a very distinguished surgeon, and at the time Master. "There is no more science in surgery," Lord Thurlow is reported to have said, "than there is in butchery." "Then," replied Gunning, "I heartily pray your lordship may break your leg and have only a butcher to set it, and my lord will then find out the difference between butchery and surgery." In 1796 the Surgeons migrated from the Old Bailey to Lincoln's Inn-fields. In that year a new Bill they sought for was rejected in the House of Lords on the ground that the College premises were too far removed from the place of execution and that it would be indecent and improper to carry the bodies of deceased criminals so long a distance through the streets of London. Finally, the Court in 1797 decided to apply to the Crown, and not to Parliament, for a new charter, and although opposition was again offered it proved unsuccessful, and on March 22nd, 1800, the Royal College of Surgeons in London was established by charter of King George III. This charter gave the College its former rights on condition of resigning its municipal privileges. The titles of "Master" and "Governors" were retained for a time, but a supplementary charter from King George IV. in 1821 replaced these by those of "President" and "Vice-Presidents." In 1843 another charter, granted by Her Majesty Queen Victoria, changed the title to that of "Royal College of Surgeons of England, with a President, two Vice-Presidents, Council, Fellows, and Members, as they exist at the present time. Thus it was that the Royal College of Surgeons of England was created.

It would seem in consonance with the tenor of this address, and calculated to identify this College as far as may be with the progress of surgery in England during the last 100 years, if I append a brief record of the life and work of those men who have during that period presided over its destinies, men who for the greater part have occupied a foremost position in their day, many of whom have achieved the highest honours and have each in turn devoted time and labour, often in a conspicuous degree, to further the interests of this College and thereby the advancement of the entire profession.

During the century of its existence this College has witnessed discoveries which have profoundly changed the character of surgical practice and the scope of surgical aspirations. An immense development has been effected in the operative surgery of every region of the body, and the victories of the surgeon over disease and death are without end. John Hunter and many of the older surgeons regarded operations as somewhat of an opprobrium to surgery and as a confession of failure. How far otherwise it is now! Intra-cranial, intra thoracic, and intra-abdominal operations are successfully carried out, many of them by proceedings which had never previously been imagined even by the boldest amongst us. A great impetus has been given to conservative methods in surgery, and the preservation of life and limb is now attainable in cases innumerable, and of the most different description, where conservation was previously regarded as impossible. How largely, also, have physicians and surgeons alike developed and cultivated that highest form of conservation, the conservation of the race in the happiness and vigour which are associated with physical health. Plastic methods have been perfected in an extraordinary degree. I would only mention as a striking although common example, the union of the ends of an accidentally divided nerve and the re-establishment of its function. Although the number and variety of operations have multiplied a hundredfold, the skill and fertility of resource exhibited in their performance have equally increased and the measure of success which has been realised, whilst it rewards and gratifies the surgeon, will appear, even to the educated layman, as little short of miraculous. In the early part of the century the surgeon knew of but a limited number of operations and for the most part those only were performed which appeared to be inevitable. He knew by sad experience how generally fatal important operations and cases of severe injury were when treated in hospital wards. His patients were more than decimated by infective diseases—pyæmia, septicæmia, erysipelas, tetanus, and by suppuration, hectic, and gangrene. He recognised, and could to some extent control, these scourges, but of any effective manner of dealing with them he knew nothing. Now we possess an intimate knowledge of the essential causes of many of these diseases, and if we cannot always cure them we can do much to prevent them. Some things have hitherto baffled our efforts. The cause and the cure of cancer are as yet unknown. We possess some crude ideas about the exciting causes of the disease and attempt with indifferent success to cure it by timely extirpation. Let us hope that the new century will still be young when some surer means of dealing with this terrible and increasing malady is discovered. A notable feature of our time is the development of the museums which are now attached to most of our public institutions. Those which more immediately concern ourselves illustrate everything within the range of biological science, and foremost amongst them all is our own great collection.

Much more might one say, and much certainly there is to say, but I will only repeat that our welcome to you all is sincere and heartfelt, and most especially so to our foreign colleagues. Our science knows no narrow national boundary. It is the common property of us all. We desire to sympathise with our fellow-workers abroad and to appreciate their work, as we trust and believe that they appreciate ours. In this address I have ventured to urge that we are much beholden to those who have gone before. In but a few years all who are now present will also belong to the past. Let us hope that, as we have not altogether forgotten those who preceded us, we, too, may be remembered a little by those who are to follow.

On great occasions like the present one the older seats of learning and other public institutions had power to grant honorary distinctions. Formerly we possessed no such faculty, but by the act of Her Gracious Majesty we, too, have recently obtained permission to grant a certain number of Honorary Fellowships of this College. The Fellowship is the greatest distinction it is in our power to bestow, and we regard it as the highest purely surgical qualification obtainable in this country. It is, therefore, a great privilege and pleasure for me to present, in behalf of this College, this high honour to those distinguished men who are about to receive it. I am sure also all present will be gratified to learn that His Royal Highness the Prince of Wales has graciously consented to become the first of our Honorary Fellows. His Royal Highness has always shown his interest in the College, and has evinced a special care for the success of its centenary. It is quite fitting, therefore, that His Royal Highness, who is the patron of so many learned and scientific societies, should add the lustre of his name to the Royal College of Surgeons of England.

(To be continued.)

BRISTOL LUNATIC ASYLUM.—The new wing of the Bristol Lunatic Asylum is now completed. It consists of four wards, which will provide accommodation for 150 female patients, and also rooms for the nursing staff. A small hospital for infectious diseases, fitted with six beds, three for each sex, had also been added. The institution will now afford accommodation for about 1000 patients. The estimated cost of the new buildings is £45,000.

ADMISSION OF THE PRINCE OF WALES TO THE HONORARY FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A DEPUTATION consisting of Sir William Mac Cormac, Bart., K.C.V.O., the President of the College; Mr. John Langton, F.R.C.S. Eng., Mr. Henry Morris, F.R.C.S. Eng., Vice-presidents; Mr. Thomas Bryant, F.R.C.S. Eng., past President and Senior Member of Council; Mr. Edward Trimmer, M.A., the Secretary; and Mr. Sibert Cowell, B.A., the assistant secretary, attended by appointment on Tuesday, July 24th, at Marlborough House for the purpose of presenting to the Prince of Wales the diploma of the Honorary Fellowship of the College to which His Royal Highness was elected on June 14th, 1900.

Sir WILLIAM MAC CORMAC, after introducing the members of the deputation, addressed His Royal Highness as follows:—

YOUR ROYAL HIGHNESS,—It is my great pleasure and privilege to-day, as President of the Royal College of Surgeons of England, to confer upon your Royal Highness the title and distinction of Honorary Fellow of our College. When this question was first mooted, nearly three years ago, we discovered that we did not possess the power to confer any honorary degree. Since then a new Charter has been procured and Your Royal Highness having graciously acceded to our wishes that you should become associated with our Corporation, I now in the name and by the authority of the Royal College of Surgeons of England, admit you an Honorary Fellow of the College.

And now, Sir, that you have become a Fellow of our College, permit me to tender to you our most respectful congratulations. You have on many occasions shown your interest and sympathy with our work, and what has happened to-day is not likely to diminish that interest. We are sure that the intimate association of your illustrious name with our College is an event in its history of the greatest importance, and cannot fail to be an encouragement in the future to all those who are connected with it.

Sir William MacCormac then handed to the Prince a Diploma on vellum engraved with the College arms, impressed with the College seal, and inscribed in the following terms:—

"Know all Men by these Presents that We, the Royal College of Surgeons of England, do hereby admit His Royal Highness Albert Edward, Prince of Wales, Duke of Cornwall, K.G., &c., &c., &c., &c., an Honorary Fellow of the College.

"As Witness our Common Seal this fourteenth day of June, 1900. "WILLIAM MAC CORMAC, President.

"HENRY G. HOWSE, "JOHN TWEEDY } Vice-Presidents.

"Enrolled by EDWARD TRIMMER, Secretary."

The Prince having accepted the Diploma expressed in courteous terms the pleasure it gave him to become an Honorary Fellow of the Royal College of Surgeons, the centenary of which was about to be celebrated. His Royal Highness, as the first Honorary Fellow of the College, having signed his name on the "Roll of Honorary Fellows," afterwards took leave of the President and officers, and the deputation withdrew.

FACTORIES AND WORKSHOPS IN 1899.

I.

THE exhaustive annual report of the Chief Inspector of Factories and Workshops for the year 1899 has just been issued by the Home Office and contains, as usual, much that will repay perusal by those interested in the health of the community and the means taken to safeguard it. Dr. Arthur Whitelegge, the chief inspector, in his interesting summary of the year's work of his department, tells us that 1899 was a busy year with many changes. Trade generally was active, involving the registration and inspection of more premises and an increase in the number of accidents to be investigated, heavier lists of casualties being always expected in times of industrial activity. With regard to these we find from a table appended that the accidents reported to certifying surgeons under the Factory and Workshop Act amounted in 1897 to 15,985, in 1898 to 19,227, and in 1899 to 22,771, these totals including fatal and non-fatal accidents occurring to both male and female workers; while the 22,771 accidents of 1899 include 871 fatal accidents, 858 to males and 13 to females, and the 21,900 non-fatal accidents for the same year comprise 18,758 to males and 3142 to females. These figures give some idea of the relative amount of danger from accidents which is run by the two sexes in our trades and manufactures. We note with regret that a decrease in accidents to children observed in 1897-98 was not continued, there being, on the contrary, some increase in 1898-99. Dr. Whitelegge further points out that while the minor accidents reportable only to the inspectors increased 25·2 per cent., from 38,335 to 47,989, the number reported also to certifying surgeons advanced 18·4 per cent., from 19,227 to 22,771, and the fatal accidents 19·8 per cent., from 727 to 871. On the whole, therefore, he observes, the increase was less marked in the more severe forms of injury, but only under the head of "Loss of sight" was there actual decrease, and in that group the numbers are small, reference to the tables showing that loss of sight was recorded in 53 cases in 1898 and in 47 cases in 1899. With regard to the compulsory notification of certain forms of industrial poisoning under section 29 of the Factory and Workshop Act of 1895 the tables and details given show that cases of plumbism were on the whole fewer, which was mainly owing to the decrease in the number of cases reported as occurring in, and in connexion with, potteries. Under some of the sub-heads under which occur other trades in which lead in various forms is a source of danger diminution is also observable. Such sub-heads are "Glass-making," "File-cutting," and "Smelting." There was increase, however, in lead poisoning in some industries, especially in the manufacture of white lead and paints and colours, and in the miscellaneous group of minor lead industries. For the third year in succession there was no reported case of industrial arsenical poisoning. In the case of phosphorus necrosis also it is satisfactory to learn that fewer instances were reported, but anthrax seems to have increased and to have become unusually prevalent. Anthrax arises in dealing with horsehair, hides, and skins, and the degree of danger appears to vary markedly with the various sources from which these are imported, the worst country in respect of anthrax being conspicuously China. Mercurial poisoning occurs in the report for the first time, the Home Secretary having availed himself last year of the power given by Section 29 to place diseases traceable to mercurial poisoning in a factory or workshop among those of which notice must be given to his department.

The provisions of this Section of the Act of 1895 should be borne in mind by all medical men wherever practising. Those in large manufacturing centres are presumably familiar with them, but the medical inspector in his report in the Blue Book before us states that many elsewhere are not, such diseases as scarlet fever and their duties with regard to the notification of them being matters of everyday practice, while cases of lead poisoning are comparatively rare. The result of this is that the statistics with regard to lead poisoning are in some respects not to be relied upon as accurate or exhaustive. We may mention that the 29th Section of the Factory and Workshop Act of 1895 provides that every medical practitioner attending or called in to visit a patient whom he believes to be suffering from lead, phosphorus, or arsenical poisoning or anthrax contracted in any factory or workshop, shall (unless the notice required by the Section has previously been sent) send to the Chief Inspector of Factories at the Home Office a notice stating the name and full postal address of the patient and the disease from which in the opinion of the medical practitioner the patient is suffering. The medical man duly giving this notice is entitled to a fee of 2*s*. 6*d*. to be paid by the Home Office; by neglecting to do so he is liable to a fine of 40*s*. Care must therefore be exercised not to omit reporting a case proper to be reported, but it must be borne in mind that the illness must have been contracted in a factory or

workshop. The case, therefore, of a man who had contracted lead poisoning in coach-painting, or in burning off or removing old paint (one of the sources of danger mentioned in the report), in a factory or workshop should be notified, but that of a man poisoned in pursuing in the ordinary way the trade of a house-painter or a plumber should not. These do not come within the terms of the Factory Acts, except in so far as they may have contracted lead poisoning while performing such processes as grinding lead pigment in factories and workshops, and some friction has arisen through the necessary refusal to grant fees not authorised by the Act when lead poisoning has been reported and investigation has shown that it did not arise in a factory or workshop. The present practice at the Home Office is stated to be to assume that the practitioner can say that the patient is employed in a factory or workshop in which risk of lead poisoning may reasonably be anticipated and that he will not notify cases in which he cannot affirm this.

The extent to which lead poisoning is to be anticipated among house painters and plumbers is shown by the fact that under the conditions of limited notification mentioned 100 cases have been notified, while in addition information has been received from the district registrars of 18 cases in which lead poisoning was directly or indirectly the cause of death.

Before leaving the subject of the reports from which these useful statistics are compiled we observe that 63 certifying surgeons appointed under the Factory and Workshop Act of 1891 failed to make the report required of them under Section 19 of that Act, and that of 37 of these the appointment was cancelled owing to no satisfactory explanation of the omission being forthcoming. It is stated that the returns ultimately missing would not materially affect the figures given in the tables, so no doubt these cases arose where the certifying surgeons were seldom, if ever, called upon to perform their duties, but at the same time it is to be regretted that such returns as those before us should not be as complete and as accurate as possible. With regard to so much of the summary of the Chief Inspector of Factories and the reports of his subordinates as refer to dangerous processes and manufactures there is one matter which appears to us to be highly satisfactory. The stringent regulations which have been framed from time to time in order to minimise the danger of the workers in particular trades have evidently in many cases had the effect of abolishing the danger entirely. The regulations are possibly irksome, while the infringement of them may be attended with penalties, and either ingenuity is exercised which before lay dormant in order that the dangerous work may be done by machinery instead of by the hand of the workers, or else the process in which the employment of a poisonous substance was formerly regarded as necessary is found to be equally possible with the help of an agent that is innocuous. Match-making affords an instance of each of these changes, for we are informed in a single paragraph that in some match factories machinery is taking the place of hand labour in dangerous processes, while in one the firm has announced its intention to discard yellow phosphorus as it has succeeded in making "strike-anywhere" matches without it. Match-making, however, does not stand alone in its increasing safety; the use of lead for glazing earthenware and china lingers, the glazing being, as a rule, applied under conditions which protect the workers as far as they can be protected while lead is used, but the disuse of lead and the substitution of other glazes equally effective which do not contain it appear to be considerably on the increase and, indeed, form a hopeful feature in the report. Again, under the heading of "Industrial mercurial poisoning" we note a paragraph which informs us that the silvering of mirrors by means of an amalgam of mercury and tin (water-gilding), which was in former years the chief industrial source of mercurial poisoning, has been superseded in this country by the nitrate of silver and ammonia process. It will be seen from these instances that legislative interference with manufacturing processes with a view to protecting the health of the workers does not necessarily imply the undoing of the trade or manufacture interfered with merely because the interference is at first sight arbitrary and irksome. On the contrary, it stimulates the invention and adoption of better and safer methods, which better and safer methods must of necessity attract workmen of a better class who were deterred before by the danger of the employment.

THE LIGHT TREATMENT AT THE LONDON HOSPITAL.

MORE than three years have now elapsed since Finsen of Copenhagen introduced to the profession his method of treating lupus by means of light, and the favourable evidence obtained at his clinic is amply sufficient to justify a more extended employment of this valuable agent in the treatment of this troublesome disease. Although Professor Finsen has used his method for three years, yet it is only a little more than six weeks since any public institution in this country has been in a position to employ this therapeutic aid. The London Hospital is the pioneer in this matter, and this is due partly to the gift to the hospital by the Princess of Wales of some of the apparatus needed for its working and partly to the praiseworthy energy of the authorities of the London Hospital who have done all that can be required for the efficient working of the method. The "light cure" is carried on under the superintendence of Dr. Stephen Mackenzie and more immediately under the direction of Dr. J. H. Sequeira who attends for several hours daily for that purpose. A fair-sized ward has been set apart for the treatment and it includes dressing-rooms for the patients. The apparatus consists of an arc light surrounded by a shade so as to prevent the eyes of those present being dazzled. From this light there radiate four or more telescopes, each telescope conveying the light to one patient. The telescope contains lenses composed of quartz which has less obstructive effect on the active rays than any other refractive medium. The space between two of the constituent lenses of the telescope is filled with distilled water to moderate the temperature and an enclosing water-jacket serves still more to abstract the heat. The lenses are so arranged as to render convergent the divergent rays proceeding from the arc light, and they are brought to a focus by another lens which is held in position by a nurse. This lens is composed of two plates, which may be of quartz or even of glass, and the space between them is filled with water and may be connected with a supply so that there is a continuous replacing of the water which may have become heated by water which is cold. This cooling lens is held by the nurse and pressed by her fairly firmly on to the affected part. The object of this pressure is to render anæmic the part to be treated, as it has been found by experience that the therapeutic effect is much greater if the tissues are bloodless than if the circulation in them is proceeding normally. The active rays seem to be those which are usually called actinic, and are ultra-violet in the spectrum; they are therefore the most refractive rays, and they are accurately focussed on the part, the pressure being so adjusted that a red halo is seen surrounding a colourless centre of a little less than a shilling in size. The lens pressing on the skin may be held in position by rubber bands, but it is thus liable to shift and the employment of an intelligent nurse gives much more satisfactory results. It is, however, necessary that the nurse's eyes should be protected by coloured spectacles, as the light reflected from the lens pressed on the skin is intensely brilliant. Whenever it is necessary to readjust the position of the patient a red cloth cap is placed over the lower end of the telescope. The patient lies on a raised table or is seated in an adjustable chair the position of which can be varied so that the rays of light shall fall perpendicularly on to the skin. Each application or *séance* lasts about an hour and as each patient is treated only once a day and the department is open from 9 A.M. to 12 30 P.M. three sets of patients are under treatment every day, an interval of a few minutes being allowed between two sittings. The nurses after a little practice do not find it at all tedious to keep the compressing lens in position, exerting pressure at the same time, even though it lasts three hours each day. Great care is taken against sepsis; in order to prevent any such accident a separate pressure lens is kept for each patient and also separate parts of any other portion of the apparatus which comes in contact with him. These are kept in a series of lockers inscribed with the patients' names. Care is taken to protect the eyes and the unaffected parts of the patients' skin from the effects of the light rays. The light is provided by an arc lamp taking 60 to 80 ampères of current. This is obtained in the following

way: the public electric main is employed to work a converter which increases the ampèrage of the current from 10 to 60 or 80, while reducing its voltage from 140 to 60. The present converter is quite capable of supplying two such arc lamps as that employed at present, so that the capacity of the department could be doubled if necessary.

The same treatment can be carried out by the employment of the direct rays of the sun, and a small portion of the grounds has been shut off by a high paling from which can be hung curtains so as to exclude the gaze of the curious. The parallel rays of the sun are focussed on to the part by a large hollow lens containing an ammoniacal solution of copper which absorbs a large proportion of the heat rays. A separate lens has to be employed for each patient and a pressure lens, like that used with the electric light, is held against the affected part. There is no essential difference in the results obtained by the two methods.

The effect on the patient is in no way painful; the application itself causes no discomfort, and in so far as it is felt at all it is said by the patients to give a sensation of gentle warmth. But a few hours after the first application there is a certain amount of "reaction"; the part swells, becomes reddened, and is tender, but even then there is no real pain. This reaction varies in degree in different cases and is always seen in lupus vulgaris, but does not occur in cases of lupus erythematosus, so that it may be of some diagnostic value. As a rule it may be said that the greater the reaction there is the better the result. The beneficial effect of the treatment is often manifested within a few days, and one or two cases have occurred in which recovery ensued after only a few applications. Generally about 15 to 20 or 25 applications have to be employed before a satisfactory result is obtained. At one time an area not larger than the size of a shilling can be treated, so that if the diseased patches are extensive a prolonged course of treatment is required. The results, however, are eminently satisfactory: the skin becomes smooth, soft, and pliable, and what scar there is attracts little notice. The cases that are the most suitable are those with small recent patches of disease, but extensive chronic cases are improved, though not so rapidly. Lupus vulgaris seems to be the only disease in which the results are marked; in lupus erythematosus there is a little beneficial action, and one case of this disease is now under treatment at the London Hospital. It is early yet to speak of the permanence of the result, but Professor Finsen finds that recurrence occurs in only a small proportion of the cases, and in those a little further treatment removes the recurrent disease. When each patient is first admitted to this treatment at the London Hospital a photograph is taken and an elaborate system of notes has been devised. At the end of the treatment a second photograph is taken, and we hope in a few months' time to show the results when sufficient interval has occurred to render it probable that recovery is permanent. It is intended in a short time to provide an afternoon *séance* for paying patients if a sufficient number present themselves. Whatever may be the ultimate verdict of dermatologists on the Finsen treatment no one can deny the striking beneficial effects in lupus of this variety of phototherapy.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE following were among the principal amounts received at the Mansion House in aid of this Fund up to July 20th, when the total reached nearly £48,000:—

	£	s.	d.
Per the Chief Rabbi (including Great Synagogue, Aldgate, £254; New West-end, £134; Bayswater, £78; Central, £74; Hampstead, £69; St. John's-wood, £34; South-east London, £34; Dalston, £24; East London, £22; Maiden-lane, £20; New Dalston, £20	924	0	0
St. Mary Abbot's, Kensington, Parish Church	314	0	0
St. Paul's, Vicarage-gate	126	0	0
Christ Church, Victoria-road	97	0	0
Church of the Annunciation, Marylebone	286	0	0
West London Synagogue	205	0	0
Christ Church, North Brixton	82	0	0
Corporation of the City of London	105	0	0
St. Thomas's, Telford-park	22	0	0
Holy Trinity, St. Marylebone	65	0	0
St. John the Baptist, Leytonstone	20	0	0
St. Alban the Martyr, Holborn	40	0	0
St. Philip's, Sydenham	28	0	0
Box outside Mansion House	11	0	0

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6486 births and 3662 deaths were registered during the week ending July 21st. The annual rate of mortality in these towns, which had been 14·5 and 15·6 per 1000 in the two preceding weeks, further rose last week to 16·4. In London the death-rate was 16·1 per 1000, while it averaged 16·7 in the 32 provincial towns. The lowest death-rates in these towns were 10·0 in Huddersfield, 10·7 in Cardiff, 11·6 in Burnley, and 11·7 in Bristol; the highest rates were 21·0 in Manchester, 22·2 in Salford, 23·0 in Sunderland, and 23·6 in Liverpool. The 3662 deaths in these towns included 555 which were referred to the principal zymotic diseases, against 344 and 427 in the two preceding weeks; of these 214 resulted from diarrhœa, 118 from measles, 91 from whooping-cough, 69 from diphtheria, 37 from "fever" (principally enteric), and 26 from scarlet fever. No fatal case of any of these diseases occurred last week in Plymouth; in the other towns they caused the lowest death-rates in Burnley, Halifax, Bradford, and Gateshead, and the highest rates in Derby, Salford, Leeds, and Sheffield. The greatest mortality from measles occurred in Derby, Oldham, Huddersfield, and Sunderland; from scarlet fever in Blackburn; from whooping-cough in Liverpool, Bolton, and Blackburn; and from diarrhœa in West Ham, Birkenhead, Liverpool, Salford, Leeds, and Sheffield. The mortality from "fever" showed no marked excess in any of the 33 towns. The 69 deaths from diphtheria included 21 in London, 10 in Sheffield, six in Leicester, and five in Leeds. No fatal case of small-pox was registered last week either in London or in any of the 32 provincial towns. The number of small-pox patients in the Metropolitan Asylums Hospitals, which had been 17 at the end of each of the two preceding weeks, had declined to 14 on Saturday last, July 21st; one new case was admitted during the week, against four in each of the two preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1877, against numbers increasing from 1754 to 1861 on the six preceding Saturdays; 222 new cases were admitted during the week, against 210, 229, and 208 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 140 and 160 in the two preceding weeks, further rose last week to 169, but were slightly below the corrected average. The causes of 39, or 1·1 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bolton, Oldham, and 10 other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Salford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·9, 17·7, and 17·2 per 1000 in the three preceding weeks, rose again to 19·0 during the week ending July 21st, and exceeded by 2·6 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·5 in Perth and 14·3 in Dundee to 19·7 in Greenock and 22·2 in Glasgow. The 588 deaths in these towns included 38 which were referred to diarrhœa, 22 to whooping-cough, 18 to measles, 11 to "fever," six to diphtheria, five to scarlet fever, and two to small-pox. In all 102 deaths resulted from these principal zymotic diseases, against 85 and 73 in the two preceding weeks. These 102 deaths were equal to an annual rate of 3·3 per 1000, which was 0·8 per 1000 above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 32 and 23 in the two preceding weeks, rose again last week to 38, of which 23 were registered in Glasgow, four in Edinburgh, and four in Dundee. The deaths from whooping-cough, which had been 22 and 21 in the two preceding weeks, rose again to 22 last week, and included 16 in Glasgow, two in Aberdeen, and two in Paisley. The fatal cases of measles, which had been 20 and 17 in the two preceding weeks, rose again last week to 18, of which 10 occurred in Glasgow and six in Edinburgh. The deaths referred to different forms of "fever,"

which had declined from four to none in the three preceding weeks, rose again to 11 last week and included 10 in Glasgow. The fatal cases of diphtheria, which had been two and four in the two preceding weeks, further rose last week to six, of which three were registered in Glasgow and three in Edinburgh. The deaths from scarlet fever, which had been four and seven in the two preceding weeks, declined again to five last week, and included two in Glasgow and two in Edinburgh. The two fatal cases of small-pox were both registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 97 to 71 in the three preceding weeks, rose again last week to 80, and were 22 in excess of the number in the corresponding period of last year. The causes of 29, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 17·8 and 18·2 per 1000 in the two preceding weeks, further rose to 23·4 during the week ending July 21st. During the past four weeks the death-rates in the city has averaged 19·9 per 1000, the rates during the same period being 14·6 in London and 17·0 in Edinburgh. The 157 deaths belonging to Dublin registered during the week under notice were 35 in excess of the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against three, six, and eight in the three preceding weeks; of these, five resulted from whooping-cough, four from diarrhœa, two from "fever," one from scarlet fever, one from diphtheria, and not one from either small-pox or measles. These 13 deaths were equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 2·6 in London and 2·9 in Edinburgh. The fatal cases of whooping-cough, which had been two, three, and four in the three preceding weeks, further rose last week to five. The deaths referred to diarrhœa, which had been two and one in the two preceding weeks, rose again to four last week. The fatal cases of "fever," which had been one and three in the two preceding weeks, declined last week to two. The 157 deaths in Dublin last week included 26 of infants under one year of age and 34 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons considerably exceeded the number recorded in the preceding week. Seven inquest cases and three deaths from violence were registered; and 52, or one-third, of the deaths occurred in public institutions. The causes of six, or nearly 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Samuel W. Vasey to the *Centurion*. Staff Surgeon James McC. Martin, D.S.O., to the *Barfleur*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant A. D. Jameson has proceeded to Woolwich for temporary duty.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the East Lancashire Regiment: Surgeon-Lieutenant A. Little resigns his commission. 2nd Volunteer Battalion the Essex Regiment: Surgeon-Captain S. A. Mugford resigns his commission.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Edmund Eustace Dyer, 7th Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders), to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies: Surgeon-Captain G. T. Beatson to be Surgeon-Major and to command under paragraph 55A Volunteer Regulations.

THE SOUTH AFRICAN COMMISSION.

The Commissioners have lost no time in commencing their labours. The preliminary meeting was held at the commencement of the past week at Burlington House, when the President, Lord Justice Romer, stated that although the Commission was directed to inquire into and report upon the arrangements for the care and treatment of the sick and wounded during the South African campaign they had no compulsory or special powers conferred upon them; but they hoped and believed that practically they would not be hampered in their work by not having such powers. They proposed first of all to take the necessary departmental evidence and then to obtain from unofficial witnesses in England as much information as possible bearing on the subject of the inquiry. The Commissioners hoped to leave for South Africa on Saturday, August 4th, and they would therefore in all probability not be able to complete the evidence in England before they left. He further stated that should the Commissioners find that their anticipations were not realised and that they were substantially hindered from ascertaining the facts by the absence of compulsory powers they would not hesitate so to report to the Prime Minister and to ask his assistance in procuring the necessary powers.

It is hardly necessary to remind our readers that the Commission is now composed of the following gentlemen: Lord Justice Romer (President); Dr. W. S. Church (President of the Royal College of Physicians of London), Professor D. J. Cunningham (Trinity College, Dublin), Mr. Frederick Harrison (General Manager of the London and North-Western Railway), Sir David Richmond (ex-Lord Provost of Glasgow), and Major Tennant (secretary).

The following have been examined as witnesses:—Surgeon-General J. Jameson, C.B. (Director-General A.M.S.), Lieutenant-Colonel Johnston (Assistant-Director A.M.S.), Major W. G. Macpherson, R.A.M.C. (Deputy-Assistant Director A.M.S.), Lieutenant-Colonel J. S. Cowans (Deputy-Assistant Quartermaster-General), General Sir Henry Brackenbury (Director-General Ordnance Department), Colonel Steevens (Principal Ordnance Officer), Sir Ralph Knox (Under-Secretary of State for War), Colonel Stirling Ryerson (Canadian A.M.S.), Rev. W. H. Orford, Sir Howard Vincent, M.P., and Mr. Watson Cheyne, F.R.C.S. We hope to report the proceedings at some length next week.

THE RELIEF OF KUMASI.

A telegram has been received by the Colonial Office from Colonel Willcocks dated "Bekwai, July 20th," in which he says: "I left Kumasi 17th July, leaving behind 150 native soldiers under Captain Eden, Lieutenant Mayne, Medical Officer Thompson, (and) Sergeant Desborough, R.A., all West African Frontier Force, and ample supplies of ammunition and of food for seven weeks, long before which I will have reinforced detachment with a force sufficient to free itself from the surrounding villages, &c. I brought away from Kumasi old garrison, most of them in hammocks, and also a great many refugees, women and children. Before departure from Kumasi had buried heaps of rotting corpses which must have been lying near fort for weeks past. I had also cut short bush and the grass which was growing up quite close to (the) walls of the fort. The work was sickening in the extreme, but at the same time all ranks helped bravely. ..... I cannot end without bringing to notice the soldierly qualities of officers and men under trials I have personally never previously known in my long experience of jungle warfare, their cheerfulness under every form of discomfort, their valour against the unseen and unknown numbers, on half rations, native soldiers without any blankets, yet always cheery. They are deserving of high praise." Amongst the names thus brought to notice is that of Dr. McDowell, Principal Medical Officer.

DEATHS IN THE SERVICES.

Surgeon-Major Arthur Croker, late A.M.D., in his 69th year.

Brigade-Surgeon Thomas William Wright, A.M.S. retired, aged 68 years, at Blackheath, on July 20th. He served in the Ashanti war in 1873–74 and retired from the service in 1882.

Lieutenant-Colonel Charles James Hislop Warden, late I.M.S. (Bengal), on July 18th, at his residence, Highbury-grove, N., aged 49 years. He entered the Indian Medical Service in 1874.

Fleet Surgeon Thomas Martyn Sibbald on July 13th, at Taku, aged 48 years. He joined the naval service as surgeon in 1876, and was surgeon of the *Shah* when, in May, 1877, she engaged the Peruvian rebel turret-ship *Huascar* off the town of Ylo. He served in the two night torpedo expeditions, and was mentioned in despatches. During the Zulu war he landed with the *Shah's* naval brigade, accompanying the Ekowe relief column, and was present at the battle of Gingihlovo in April, 1879 (Zulu medal with clasp). He became staff-surgeon in 1888, and fleet-surgeon in 1896.

THE SICK AND WOUNDED AT TIEN-TSIN.

We have as yet no sort of well-grounded assurance that our worst fears regarding the Legations at Pekin are unfounded. It is quite clear that the upheaval in China is a national one and of a very formidable character. The fighting at Tien-tsin has been serious and the losses on the part of the allies are considerable. We know but little regarding the medical arrangements. The navy has mainly supplied the medical officers. General Gaselee, as soon as he reaches China with his force from India, is to telegraph as to the suitability of Wei-Hai-Wei (our possession) for the location of a base hospital. His force is accompanied by medical officers and field hospitals from India and by a hospital ship as well as by transports capable of being used as hospital ships. Moreover, the American hospital ship *Maine* has been placed at the disposal of Her Majesty's Government. Most important of all—as a munificent expression of loyalty and good feeling—the Maharajah Sindhia of Gwalior has made the offer of a fully-equipped hospital ship for China, upon which he is willing to spend 20 lakhs of rupees. This princely offer is made on behalf of himself, his mother, and his wife, to testify their loyalty to Her Majesty the Queen-Empress.

TRANSVAAL WAR NOTES.

The following officers of the Royal Army Medical Corps have been discharged from hospital to duty:—Major C. G. Woods, Lieutenant J. W. H. Houghton, Lieutenant R. D. Jephson, Major J. G. Black, and Major A. P. Hart; also Civil Surgeon F. G. Ralston.

Major Greig, R.A.M.C., and Major Anderson, R.A.M.C., are returning home invalided in the *Avondale Castle*.

The Mayor of Devonport has inspected the military hospital, Stoke, and visited the sick and wounded soldiers, who number about 45, all the others having recovered sufficiently to leave for their homes. The mayor, who was received by Surgeon-General G. J. H. Evatt, P.M.O., Lieutenant-Colonel J. R. Rahilly, and Major C. J. Addison, R.A.M.C., distributed presents to the men. About 250 more invalids have arrived by the *Cavour* and will be accommodated in the hospital.

The steamship *Britannic* arrived at Southampton on July 22nd from South Africa. She carried 505 invalids, who were admitted to the wards of the Royal Victoria Hospital, Netley.

Telegraphic news has been received of the sudden death of Captain J. S. Stevenson, I.M.S., who was lately appointed deputy sanitary commissioner. We hope to publish an obituary notice of this very promising young officer.

Correspondence.

"Audi alteram partem."

"THE FOURTH DISEASE."

To the Editors of THE LANCET.

SIRS,—I accept without hesitation the differentiation of rubella into two distinct diseases which Dr. Clement Dukes has made. His reputation as an accurate observer and his position as an acknowledged authority on all affections to which boys are subject during the school period compel attention to his important communication on rubella, and the minute description he has given of the two diseases which have passed under this name is most convincing. I was, however, prepared for his conclusions. I have said for many years that there were at least three kinds of measles, but the casual and desultory experience of consultation work did not admit of the establishment of the differences by which they might be distinguished one from the other. More particularly it was impossible to ascertain if the different species "bred true." Now that the distinctions have been laid down I recognise their accuracy at once.

I am Sirs, yours faithfully,

Brook-street, W., July 25th, 1900. W. H. BROADBENT.

To the Editors of THE LANCET.

SIRS,—Whilst writing a short note on the clinical contrasts of scarlatina and scarlatiniform erythema my attention was called to Dr. Clement Dukes's article entitled, "On the Confusion of Two Different Diseases under the Name of Rubella (Rose-rash)," published in THE LANCET of July 14th (p. 89). The publication of that article has made more patent to my mind a probable fact which I have for some time suspected—viz., that scarlatina is frequently diagnosed erroneously owing to forgetfulness of the existence of a disease comparatively recently described by Brocq as "erythema scarlatiniforme desquamativum." Though I say that the disease has been recently described under this name the name only is new, since under the designation of "roseola æstiva" the same disease has long been known to us. Dr. Dukes's "fourth disease" is assuredly nothing more or less than our old friend, appearing this time without the dignity of a name. That the difficulty of distinguishing this exanthem from scarlatina is very great is evidenced strongly by the special references of many of the older authors and by modern works devoted to dermatology. More recent works on the practice of medicine are guilty of the sin of omission. The prevalence in an epidemic form of Dr. Dukes's new disease does not, I think, negative the view which I have expressed, as competent observers have related instances of epidemic roseola.

The clinical differences between cases of scarlatina and scarlatiniform erythema have been at all times little discussed, at least not sufficiently considering the importance of the subject. For some time the similarity of the simpler disease to scarlatina in most of the cases of the former which I have seen has been so great that I have considered the subject worth more attention than it commonly obtains. The ability in a given case to declare the presence or absence of scarlatina—a disease attended by so many dangers not only to the individual but to others also in his immediate vicinity—will readily be admitted to be most desirable, and yet, I fear, too often the medical man has to possibly err on the safe side and advise precautionary measures of isolation and disinfection unnecessarily. These precautionary means are at all times quite an undertaking even when necessary and are proportionately more so when directed for a passing exanthem of little importance. The most trying circumstances occur in the case of adults, amongst whom, especially in the case of middle aged females, roseola æstiva is not very uncommon during the summer months. In several cases such as I have mentioned the thermometer has registered an unexpected relatively high temperature; this fact is worth mentioning as I find that one of our best authorities on the matter particularises the fact that in the minor disease rarely does the temperature rise beyond 101° F. Instances of an elevation above this do, I believe, occasionally occur and they serve to indicate the importance of not relying too implicitly upon the thermometer as a guide in differential diagnosis here. I only record the result of my observations after most careful consideration of recent cases under my care where erythema was diagnosed and where the diagnosis was verified, in so far as it was possible to do so, by the absence of the sequelæ of scarlatina or previously acquired immunity, and from the fact that there was no resulting infection from any of them. The practical advantages of directing attention to this subject through the medium of THE LANCET consist, I assume, in recording, after mature consideration, clinical distinctions between the diseases under discussion, preferably after the method selected by Dr. Dukes, in tabular form. I do not wish to recapitulate unnecessarily, nor would I presume to an act almost amounting to a revision of so able an article by appending a lengthened table of diagnosis, but I will briefly state the results of my observations in the form of contrasted sentences.

—	Scarlatina.	Erythema scarlatiniforme.
Eruption... ...	Diffuse, punctiform; affected skin area not hypersensitive; rash when once out does not fade and reappear.	Patchy and erythematous, with well-defined borders; affected areas of skin sore to touch; rash evanescent, disappearing and reappearing in different parts of the body.
Throat	Swelling generally present, and ulceration often present.	Redness of fauces constant; no swelling or ulceration.
Glands	Sub-maxillary glands frequently markedly involved.	Sub-maxillary glands slightly or not at all affected.
Tongue	Strawberry character seldom absent.	Nothing characteristic.
Temperature...	Usually above 103° F.	Seldom reaches beyond 101° F.
Complications and sequelæ	Nephritis, otitis, &c.	None.

I have mentioned in the above table those symptoms only which, in my experience, offer a constant contrast in the two diseases. The transient rise in the temperature (never exceeding 36 hours), the enlarged occipital glands, and the coryza seem to form a combination of symptoms almost pathognomonic of rötheln; at least one would imagine sufficiently so to exclude those affections most resembling it.

I am, Sirs, yours faithfully,

ALFRED RUTTER, M.B., C.M. Edin.

Ryhope, Durham, July 16th, 1900.

To the Editors of THE LANCET.

SIRS,—May I make a suggestion to Dr. Clement Dukes as to the genesis of his "fourth" infectious disease. Living here, where there are educational centres for young people, the first two or three weeks of each term are always more or less anxious to the medical officer of such schools, and he has to act without much time for reflection on his diagnosis and isolate the sick from the healthy and so prevent or arrest the spread of epidemic disorders in the schools or district.

As a student I was taught to regard German measles as a hybrid disease between measles and scarlet fever, but like many other medical men found some cases where the diagnosis was almost impossible, and on two occasions (one in the practice of a colleague, the other in my own) the following serious accident occurred. In both cases the utmost care was taken to eliminate any source of fallacy, so much so in my case that a consultation actually was held before the patient was removed. Years elapsed between the occurrence of these cases, but in both instances the diagnosis was mild scarlet fever; they were both removed to different isolation hospitals and within a week both patients took genuine scarlet fever in the hospital. These cases were doubtless examples of this somewhat mysterious "fourth" disease alluded to in THE LANCET of July 14th by Dr. Dukes. Fortunately epidemics of this so-called "fourth" disease are rare, else more mistakes would occur at infectious hospitals.

While travelling in Spain and Portugal I was struck with the numbers of mules, the importance attached to them, and the care bestowed on their breeding. Of course the mule owes its existence to an asinine father and an equine mother, and our old friend German measles may be looked upon as similarly due to the efforts of the microbes of measles and scarlet fever. But there is another animal which is also a hybrid, which owes its genesis to an equine father and an asinine mother; this animal is somewhat rare and is known as a hinny and would correspond to the "fourth" disease.

I do not pretend to give any details as to the maternity or paternity of the microbes of scarlet fever and measles in the production of German measles, or the "fourth" disease or, as Dr. Dukes calls it, the scarlatinal form of German measles. It is generally believed that hybrid animals have no productive power, but this is not strictly true, and I have most direct evidence of a mule conceiving and bringing forth.

How German measles in both forms could propagate themselves seemed a difficulty at first, but as we descend the scale of animal existence fertility and fecundity increase at a most rapid rate, and the space in development from a horse to a scarlet fever microbe might account for the propagation of the infectious diseases and the difficulty in this direction with a mule or a hinny. Still it is well known that scarlet fever and measles are more highly infectious than those hybrid forms of disease. My object in this short note is to show that the idea of a "fourth" disease had occurred to other minds, and also that anyone who reads this may be prevented from sending a case of "fourth" disease to be treated at a scarlet fever hospital. I have suspicions of another hybrid disease which I hope to refer to on another occasion.—I am, Sirs, yours faithfully,

THOMAS JOHNSTONE, M.D. Edin., M.R.C.P. Lond.

Ilkley, Yorks, July 25th, 1900.

To the Editors of THE LANCET.

SIRS,—If the views given by Dr. Dukes in THE LANCET of July 14th, p. 89, be reliable one important result must not be overlooked. Free desquamation alone will not be a sufficient warrant for a diagnosis of scarlet fever in the absence of a clear history and no other sequelæ. Many a medical man who in days gone by has notified such a case straight away and regarded himself as a public benefactor will in future sit on the fence and do nothing of the sort. There has been an impression abroad that however one might be misled by sore-throats and rashes there was a haven of certainty in "free desquamation." I confess to being rather glad that this haven has been bombarded, and I would like to put another missile into it by insisting that even in measles there may be protracted and free desquamation. Such a case happened to me the other day. Two girls (twins) had ordinary measles with catarrhal symptoms and in one case severe dysenteric diarrhœa. In one of these cases desquamation was going on so vigorously a month afterwards that another medical man who accidentally saw it had an overwhelming suspicion of scarlet fever. Holt is the only author I can find who mentions that the desquamation in measles may be protracted—and even he only allows two weeks—yet here is a clear case of over a month.

I am, Sirs, yours faithfully,

July 25th, 1900. GERALD S. WALTON, M.B., C.M. Edin.

THE APPOINTMENT OF SPECIAL MEDICAL OFFICERS FOR THE CERTIFICATION OF LUNATICS.

To the Editors of THE LANCET.

SIRS,—Now that the "St. Pancras Scandals" have brought up the important subject of the certification of lunatics I think it is a very fit time to make a few suggestions concerning such notification and also as to the after-responsibility of people who have been inmates of lunatic asylums.

In the first place I would suggest that medical officers should be appointed for various districts, as in the case of the medical officer of health, with a fixed salary per annum (and not by the number of cases certified); moreover the medical officer should not be in private practice, so that his opinion on any case would not be biased in any way on account of being afraid of offending patients and their friends. Also such medical officers should have had previous experience in asylums, so as to be in a position to give an expert opinion on the mental condition of any person they might be called upon to certify, and in that way many patients suffering from the delirium of various diseases, such as alcoholism, meningitis, &c., would not be sent (long distances in many cases) to asylums for treatment when they should have been sent to a hospital or infirmary, and their friends, moreover, would be saved much pain and anxiety. Another important point that would tend to prevent patients from travelling in an unfit state would be a rule that every medical officer certifying a patient should see that patient not more than 48 hours previously to admission into the asylum. It would not be out of place to mention that many medical men have never certified a case and if called upon to do so would be at a loss to know what are the chief points to inquire into before certifying that a person ought to be under proper care and control, and, finally, some medical men refuse altogether for fear of prosecution. Such medical officers would also be expected to inquire into the family history of each patient and to observe the kind of home they have, their mode of life as regards drink, sexual habits and excesses, with whom they reside, and the manner in which they are treated by their friends, the knowledge of such matters often being of great importance in certain cases so as to be able to judge if statements made by patients with regard to the treatment they have received, the owning of property and money, are really delusions or not. Also that the medical officer should be present when the patient is interviewed by the magistrate so that if there was any doubt as to the patient's sanity it could be thoroughly inquired into before he was sent to an asylum. In some cases, such as mania following a drinking bout (the patient often recovering in a few days), there is no need to send them to asylums for treatment; in fact, if they were sent anywhere, a home for inebriates or a prison would have a better effect in suppressing such cases.

The above information about patients would also be of great help to the superintendents of various asylums when the subject of the discharge of a patient is under discussion, since it is very important in certain cases to know if he would be properly looked after for the first few weeks after leaving an asylum. Again, while the patients are on "trial" (before being finally discharged) such medical officers should

visit them from time to time, and in the case of a patient showing a relapse at once have them removed to the asylum again; in that way many accidents might be avoided. It might be mentioned here that in cases of medical men certifying their own patients they have occasionally been subjected to much annoyance by violence from such people after their release from an asylum which would probably not happen in the case of an independent certifying medical officer. Another important point is the obtaining of work for patients recently discharged from asylums, in which endeavour they might be materially helped by such medical officers, who would probably be in touch with members of town councils, &c.

Finally, there are many cases of insanity brought to the notice of the police owing to the eccentricities or violent habits of patients, and many accidents might be avoided if in such cases an expert in mental diseases was at once called upon to make an examination. To be able successfully to obtain all these various pieces of information without causing undue offence or annoyance to patients and their friends would in many cases require much patience, tact, and judgment, but I think asylum training, especially if combined with some experience of private practice, should enable a man to cope with the majority of cases.

I am, Sirs, yours faithfully,

Hatton, near Warwick, July 23rd, 1900. O. POLHILL TURNER.

LEADLESS CERAMIC ENAMELS.

To the Editors of THE LANCET.

SIRS,—On Nov. 19th, 1898, at page 1338, and again on Jan. 7th, 1899, at page 49, you were kind enough to notice my efforts towards the discovery and practical introduction of leadless glazes, and as you have referred to the recent Parliamentary debate on lead poisoning I should like to point out an error that some persons fall into by assuming that the general use of leadless glazes would of itself entirely remove the liability of pottery employés to contract plumbism.

Reference to statistics shows that such persons as ground-layers and litho-colour dusters yield quite a large proportion of cases, and yet they do not handle the glaze in a free state; what these people use are the *enamel colours*, which are almost invariably compounds of *fritted* lead with borax and colorant oxides (see pages 7, 8, 9, and 40 of the report by Dr. Thorpe and Dr. Oliver). To meet such cases I have for many months been laboriously experimenting with the object of discovering leadless ceramic enamels, and now I submit some specimens which, although willingly admitted to be more or less defective, are nevertheless sufficient evidence that such enamels will ultimately be practicable. Then, and not until then, will it be possible to entirely dispense with lead compounds and thus completely eradicate plumbism in potteries.

I am, Sirs, yours faithfully,

WM. J. FURNIVAL.

Granville-terrace, Stone, Staffs, July 17th, 1900.

A MEMORIAL TO THE MILITARY AND CIVIL MEMBERS OF THE MEDICAL PROFESSION WHO HAVE LOST THEIR LIVES IN THE SOUTH AFRICAN WAR.

To the Editors of THE LANCET.

SIRS,—The Princess Christian Convalescent Homes for Soldiers and Sailors, now in course of erection at Bisley, will soon be available for use. Many of the beds have already been endowed. The Queen has given two beds, the Duke and Duchess of York one bed for a soldier or sailor, the Princess Christian one for the King's Royal Rifles, and Princess Victoria of Schleswig-Holstein and Princess Aribert of Anhalt one bed for a "green-jacket," &c. Princess Christian has suggested to me her wish that a bed should be endowed for the sole use of the non-commissioned officers and men of the Royal Army Medical Corps. I proposed that the bed should be endowed as a memorial to the members of the medical profession, both military and civil, who have lost their lives in the war in South Africa. The ready response which I have received from a few friends to whom I applied privately, encourages me to hope that the scheme will commend itself to the medical profession generally. The amount required for the permanent endowment of a bed is £600, and towards this the Committee of the R.A.M.C. South Africa Fund has voted £200. From other sources I have received £125, and I now venture to appeal to the medical profession to make up the amount required (£275). I append a first list of subscriptions. Cheques or postal orders should be made out to Mrs. Meredith, and crossed "Barclay & Co., Princess Christian Bed." The fund, when completed, will be handed over to the trustees appointed for all the endowed beds.

I am, Sirs, yours faithfully,

CAROLINE S. MEREDITH.

21, Manchester-square, W., July 23rd.

PROFESSOR LUSTIG'S PLAGUE SERUM.

To the Editors of THE LANCET.

SIRS,—As a new series of observations with Professor Lustig's curative serum was in progress at the Arthur-road Hospital I did not intend troubling you with any communication on the subject until it was completed. But as your Special Correspondent in India, who seems to have taken the serum treatment of plague under his kind, too kind, protection and considers himself the sole arbiter of its destinies—never so happy as when sounding its death-knell and from which he appears to derive a sort of malign pleasure—is again on the warpath, the interests of truth, no less than those of science and humanity, demand that the true facts bearing upon this most vital question should be placed before your readers.

In the issue of THE LANCET of June 2nd (p. 1608) there appears from the pen of your correspondent a critique on a paper read by Dr. Alfons Mayr of the Municipal Laboratory at Bombay, wherein the various issues and conclusions arrived at by the author are so confused and mixed up by him as to prejudice those not conversant with the subject against this line of treatment and to create a distinctly unfavourable impression. And it is with a view to remove this unjust and unfair prejudice and wrong impression that I have ventured to trespass on your space, especially as I have personally conducted all the observations on the serum treatment and am solely responsible for the results achieved up to now. Dr. Mayr's paper was based, in fact, entirely upon the monthly reports submitted by me officially to the municipal corporation and such other records as I placed at his disposal.

Professor Lustig reached Bombay in June, 1897, after the first epidemic of plague had ran its course. A few sporadic cases, however, existed, and these were placed at his disposal for treatment with a curative serum he had brought with him from Florence. The results proved extremely satisfactory. As material for further observation was not available in Bombay he proceeded up country and treated some 30 cases with results equally satisfactory. When, some time after his return to Florence, he learnt that another epidemic had broken out, he offered to prepare and send down some serum with a view to test its efficacy on a sufficiently large scale, and it is needless to say that his offer was thankfully accepted by the corporation. Early in March, 1898, Dr. (now Professor) Galeotti and Dr. Poluctinci arrived in Bombay with a quantity of serum, and as the epidemic was at its height arrangements were made to begin at once with the serum treatment. As the supply of serum was to reach Bombay from time to time and at irregular intervals, and was to be limited, and as the objects then in view were to test its value on a clinical basis and to watch its effects from day to day on the more pronounced symptoms of plague, the following procedure was adopted in treating the cases. All moribund cases (those in which the action of the heart had

become gravely impaired and exhibited signs of failure or impending failure) and as also all convalescents and semi-convalescents were excluded from the treatment. The reasons for such exclusion are sufficiently obvious to all experimenters. Whenever a new mode of treatment has to be tested it is usual to eliminate all disturbing factors that tend to vitiate the final results. And as it was found from our experience of plague that the two above-named classes of cases were such disturbing factors they were excluded. The former when admitted into hospital were generally found to be beyond the reach of all possible human help, and in the case of the latter it was soon recognised that half the battle—nay, more than half and that the most important—had been already fought and won outside the hospital, and no further assistance was required. Moreover, just as the inclusion of the moribunds would not have told against the serum treatment the non-exclusion of the convalescents would have failed to convince us of its value. Nowhere, so far as I am aware, is such material selected for experiments with new methods of treatment, and in adopting this procedure there was no violent departure from the methods in vogue elsewhere—in fact, there was ample justification for it in a preliminary trial.

The first series of observations lasted from March to November, 1898, and again from February to May, 1899. During the course of this period 403 patients received the serum treatment and 1190 patients were treated by ordinary methods. The clinical effects of the serum were watched from day to day, and although in some very grave and advanced cases the patients ultimately succumbed the immediate effects on the general condition of the patients were extremely well marked, and this indicated either that the dose of the serum was too small, or that it was not strong enough, or that the treatment was commenced too late. But on the whole the improvement was quite perceptible and gratifying. When at the termination of these observations the results were tabulated it was found that the serum-treated cases had a recovery rate of 38·2 per cent., whereas that in those not so treated was 19·5 per cent. only. The latter rate was, however, not less than that of the other large public hospitals, and the combined admissions numbering 4762 in two of the largest during the same period had a recovery rate of 19·7 per cent., and thus it becomes apparent that the exclusion of moribunds and convalescents did not tell in favour of the serum by reducing to any extent whatsoever the mortality rate in those treated by ordinary methods. In fact this system of "selection" so-called or rather mis-called, was so strict and accurate as to eliminate even all mild cases, for were it otherwise the mortality rate in the serum-treated cases ought to have mounted up much higher than the average of the other hospitals.

The second series of observations was commenced in May, 1899, and is still being continued. The object with which this series was started was to determine the statistical value of the serum, and hence it was resolved to conduct observations on 1000 cases of plague, 500 to be treated with the serum and 500 by ordinary methods, the latter acting as controls, and the cases were to be taken for treatment *alternately* in the order of admission and *without any attempt at exclusion of any sort*. But objection to this method of treatment was the preponderance of either moribunds or convalescents in either set vitiating the final results. It was, however, anticipated that in two such large sets of 500 cases each these would equalise at the end, and thus no undue advantage would accrue to one side or the other. We shall see further on whether and to what extent this anticipation was justified by practical experience. Further, in order to arrive at strict accuracy and to eliminate all errors some standard had to be fixed as to what cases should be classed as moribunds and as convalescents. It was therefore determined to fix the limit for the former at 24 hours, and all patients dying within 24 hours of admission were considered as moribunds, but it was subsequently found that a large number died between 24 and 27 hours of admission, and hence 27 hours was adopted as the standard. As regards convalescents,[1] all those that had gone over the acute stage of the disease and had a normal temperature or thereabouts and had suppurating or suppurated and open buboes were considered convalescent.

And now as to the results. Up to the end of last month 480 cases have been treated with the serum, and 480 cases have become their controls, under ordinary treatment:—

	No.	Died.	Recovered.	Percentage of mortality.	Percentage of recovery.
Serum cases	480	328	152	68·33	31·67
Control cases	480	382	98	79·58	20·42

The serum cases show a recovery rate of 31 67 per cent., whereas the controls have a rate of 20·42 per cent., a difference in favour of the serum of 11 25 per cent. But the above results are not strictly accurate, and have been rendered fallacious by the undue preponderance of moribunds and convalescents in each series. The anticipation at first entertained about the equalising of these has not been realised in actual practice and thus an element of error has been introduced into the statistics. The 480 serum cases were found to include 139 moribunds and 28 convalescents, whereas the controls had 145 and 38 respectively. The former had an advantage over the latter of six less moribunds, whereas the latter were better off in convalescents by 10. Hence for a strictly accurate comparison, the only course open is to eliminate all the moribunds and all the convalescents from either series, and then deduce results from those remaining. If that is done, the results stand as below.

	No.	Died.	Recovered.	Percentage of mortality.	Percentage of recovery.
Serum cases	313	189	124	60·38	39·62
Control cases	297	237	60	79·79	20·21

The percentage of recovery stands thus at 39·62 per cent. for the serum cases, and 20·21 for the controls, a difference of 19·08 per cent. in favour of serum. These results clearly indicate the value of serum treatment in those cases that are really acute and fit for treatment, and show that in these it is possible to very nearly double the recovery rate by the use of serum. These differences in the percentages do not, however, show the full value of the serum treatment, and that could only be arrived at by following the method adopted by Professor Haffkine in determining the life-saving value of his prophylactic inoculations against plague. That system is based on calculating the relative ratios of mortality amongst the inoculated and non-inoculated, and if the same system be adopted for the serum treatment the ratio of recovery in the serum cases as to control cases would be as 1 of control to 1·55 of serum in *all* cases, and 1 to 1·96 when the moribunds and convalescents are excluded from both the series. Or to put it in another way, if 100 cases out of a given number recover under ordinary treatment the same number if treated with the serum would give 155 recoveries. And therefore the percentage of recovery is enhanced in one case by 55 per cent. and by 96 per cent. in the other.

These, Sirs, are the plain and unvarnished facts with regard to the use of Professor Lustig's serum in the treatment of plague and they place before the reader the truth, the whole truth, and nothing but the truth. We have no reason to be dissatisfied with the progress made within two years of its application. Neither the mode of its preparation nor its application at the bedside have yet been finally determined and it is only by further research, experiment, and prolonged clinical observation that we shall be enabled to place it on a proper basis. So far as we have gone we have been able to prove that the serum treatment is the only treatment that can in any way appreciably reduce the high mortality of plague and we abide by our experience. When the diphtheria antitoxin required more than a decade for its perfection is it not reasonable that sufficient time should be allowed for the application of a serum against a much more rapidly fatal and more deadly disease like plague? And is it demanding too much of special correspondents to ask them to withhold awhile their *obiter dicta* and let those best conversant with the subject to work out, quietly and undisturbed, their destiny until they reach their goal, which has but one and only aim in view—viz., the lessening of human suffering and the saving of human life?

I am, Sirs, yours faithfully,

N. H. CHOKSY, M.D.
Chief Medical Officer, Arthur-road Hospital.

Bombay, July 7th, 1900.

[1] All those that were taken as convalescents in both the series ultimately recovered, and there was not a single death amongst them.

"RODENT CANCER OF THE CORNEA."

To the Editors of THE LANCET.

SIRS,—The interesting case published under the above title by Mr. Sydney Stephenson in THE LANCET of July 21st

would have been much more valuable had the diagnosis of cancer been verified. Judging from Mr. Stephenson's description and diagram the characters of the disease in his case agreed so closely with those of the well-known though somewhat rare chronic creeping ulcer of the cornea, in which there is, I believe, no suspicion of malignancy, that one is compelled to ask in what particulars Mr. Stephenson's case differed from the type? It has always seemed to me unfortunate that the term "rodent," already in use for a form of cancer of the skin, should also have come into use to designate this form of corneal ulcer. If Mr. Stephenson's case were cancerous one can only say that rodent cancer of the cornea, though not hitherto recognised, cannot be very uncommon, for the form of corneal ulcer apparently illustrated by Mr. Stephenson's case is described in most of the standard works on diseases of the eye. The galvanic cautery vigorously applied to the extending border seems to succeed better than any other treatment, but some cases baffle all attempts at cure.

I am, Sirs, yours faithfully,

July 25th, 1900. E. NETTLESHIP.

"ARSENIC IN SODIUM PHOSPHATE."

To the Editors of THE LANCET.

SIRS,—In your criticism of the above case contained in your issue of July 21st, p. 208, after stating the fact that we can supply phosphate of soda free from arsenic, you say: "It is a pity, we think, that if, as these druggists state, they knew of the important impurity they did not give greater and earlier publicity to the fact." As manufacturing chemists we certainly do not feel it our duty to warn the public, the medical profession, the wholesale chemists, or other manufacturing chemists of impurities not provided for by the British Pharmacopœia and contained in the products they are interested in. Our duty appears to us to be in making our articles free from these impurities and of the highest standard of purity.

We are, Sirs, yours faithfully,

MAY AND BAKER, LIMITED

(per W. E. B. Blenkinsop, Managing Director).

Battersea, S.W., July 24th, 1900.

"THE COMPARATIVE GERMICIDAL ACTION OF SOME DISINFECTANTS."

To the Editors of THE LANCET.

SIRS,—My attention has recently been drawn to a paper under the above heading in THE LANCET of June 23rd (p. 1797), by Mr. Arthur H. Burgess of Manchester, and I write to point out that the comparative results obtained by him are greatly at variance with those of other observers and that in my opinion this discrepancy is due to the method which has been employed in arriving at these conclusions. The thread method was formerly much used, but as far as I am aware is seldom employed now as it was found to give discordant results. In my own practice I have given it up almost entirely, except in testing spore-bearing organisms under certain conditions and also in experiments on gaseous disinfection, owing to the uncertainty of its results and the difficulties of manipulation.

One of the difficulties attending the thread method is that due to grease, and Mr. Burgess in his paper does not mention whether he took precautions to ensure the freedom of the threads from grease, as he only refers to sterilising them before use. The most important error, in my opinion, arises from the fact that when the threads are partially dried without any attempt being made to remove the organic matter of the broth emulsion, a film of dry albuminous matter is formed which protects the organisms, and that therefore I cannot agree with Mr. Burgess when he says that "the bacilli are freely exposed to the action of the disinfectant in solution, no albuminous matter being present." Another point which is worth bearing in mind is the fact that it is almost impossible to conduct a series of inoculations in such a short interval as one minute, and if Mr. Burgess used different cultures for his one-minute experiments then the results are not strictly comparable. I notice that his sub-cultures were incubated for 10 days. This time seems unduly prolonged, as with most cultures of bacillus coli communis a growth or turbidity occurs in a much shorter time than that when kept at blood heat. The method described by Mr. J. T. A. Walker in his letter[1] is one which I have employed for some years in a slightly modified form, and I believe it to be at present that which gives the most regular and constant results, and it would be interesting if Mr. Walker would publish in your journal the experiments referred to in his letter as they could then be compared with the results obtained by Mr. Burgess.

I am, Sirs, yours faithfully,

SAMUEL RIDEAL.

Victoria-mansions, Westminster, S.W., July 25th, 1900.

PLAGUE IN TURKEY.

(FROM A CORRESPONDENT.)

FOR some months past plague has been present in more than one portion of the Turkish Empire, but up to the present it has nowhere given rise to anything of the nature of a severe epidemic. The outbreak which has naturally caused the greatest apprehension has been that in Smyrna, on account of the size and importance of the town, of the amount of shipping constantly visiting the port, and of its proximity to Constantinople. Fortunately, the outbreak has so far been of a very mild character, only 17 cases in all having been reported in the course of over two months. But the slowness with which plague takes hold of a place is a well-known character of the disease, and bearing the example of Calcutta and other places in mind it is impossible not to feel some degree of apprehensiveness for the future behaviour of plague in Smyrna.

The first recognised case of the disease there was seen on May 7th, when the patient had already been ill some few days. The patient was an elderly Jew, 60 years of age, living apparently in very poor circumstances. The second case occurred on May 26th, or nineteen days after the recognition of the first case. This patient was also a Jew, a youth, aged 23 years, who occupied a *khan* some quarter of a mile away from that occupied by the first patient; he was taken ill apparently on May 25th. Another short interval without a case followed, but on the night of June 4th–5th a third person fell ill with the disease. This was a boy, an Ottoman, aged 14 years, acting as domestic servant in the Ski-Tchesmelik quarter, a long way from the part of the town where the other patients had lived. The fourth case was also that of a Turk, a man aged 45 years, who lived outside the town of Smyrna, on a hill called Mount Bech-Tepé, where a few people dwell in a small group of isolated huts. He was first seen on June 15th, but the date of his attack is uncertain. All these four persons suffered from the disease in a remarkably mild form and all recovered. In each the diagnosis was made certain by the isolation of the plague bacillus from the bubo. In none could any direct connexion with a previous case of the disease be traced. The fifth case, on the other hand, ended in death, and it proved to be the first of a group of cases which occurred in and around a particular *khan* or group of houses. This is known as the Echeref-Pasha *khan* and is situated in the Bach-Durak quarter of the town. The fifth, sixth, seventh, ninth, and eleventh cases of plague were all in persons inhabiting this *khan* or its neighbourhood. The remaining cases, into the details of which it is scarcely necessary to enter, occurred in various other quarters of the town, and little or no trace of connexion could be found between the successive cases. The last was reported on July 8th; the patient had been ill since the 5th. A week has now elapsed without a fresh case being reported; this is reassuring as far as it goes, but in view of the wide extension of the infection throughout the town of Smyrna only the most sanguine can venture to hope that the outbreak is over and the infection completely eradicated. A less reassuring feature of the outbreak is the tendency shown to a successive increase in the fatality of the disease. At the outset it was of a mild character, and the first four cases all recovered, as already stated. Then followed, between June 17th and 27th, ten cases, of which three proved fatal; but on July 1st, 4th, and 8th three fresh cases were reported, every one of which proved fatal. It is interesting, in connexion with the Smyrma outbreak, that no sickness or mortality among rats has, it

[1] THE LANCET, July 21st, 1900 (p. 222).

is said, been observed. The serum treatment was employed in some of the cases with more or less satisfactory results.

At Trebizond a single case of the disease has been reported. The patient was a child, aged five years, who fell ill on June 11th. Her father was employed in the Custom House in looking after contraband goods, and it has been suggested that the infection may have been imported by means of some goods of this nature. The child had a very mild attack of the disease and for a time it was hoped that in spite of the clinical appearances it was not plague at all. The bacillus could not be found in smear specimens from the contents of the glands, but after some days it was found by means of culture and by inoculations into guinea-pigs, and all doubt as to the specific nature of the disease was thus removed. Fortunately, no subsequent cases have occurred, and it seems possible to hope that, as active measures of isolation and disinfection were at once enforced in regard to this single case, Trebizond may escape without any further spread of the disease.

In the Hedjaz plague has almost disappeared. In the week ending July 9th three deaths from the disease were reported from Jeddah and none from Yambo. In Jeddah from the beginning of the outbreak on April 26th up to July 9th the deaths from plague were in all 81; and at Yambo from April 11th to the same date the deaths numbered 67. It is noteworthy that the outbreak in Jeddah this year, as in past years, coincided with the great annual pilgrimage to Mecca and Medirah.

The remainder of the Turkish Empire appears to be for the present quite free from plague. A few cases of the disease recently occurred in the well-known endemic centre of plague in Assyr, in Arabia. Mesopotamia, on the other hand, where the disease has from time to time prevailed in past years, has this year apparently remained free from it, although in Persia, at no great distance from the Turco-Persian frontier, an outbreak of some severity has occurred within the past few months.

July 15th.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending June 9th are as follows. Remaining at the beginning of the week, 88; admitted, 4; discharged, 5; died, 3; remaining at the end of the week, 84. The totals up to the end of the week are as follows. Cases 258; deaths, 95; discharges, 89; contacts, 1512; remaining, 81; cases among contacts, seven. The Chinese are included among the above figures, of whom there were attacked 10, with eight deaths. All other patients were whites.

The number of attacks during more recent weeks having been 38, 23, 23, seven, 17, and four. It is hoped that the epidemic may now be nearing its end.

From time to time sick cats have been mentioned by owners, but on inquiry it was usually found that they had already been got rid of. Two or three have been submitted to examination, however, but the bodies of these felines have furnished no evidence of plague until this week in the case of an animal which was secured and forwarded by a medical man and which was dying at the time of its being received. Having been killed with chloroform, it was found that the cervical glands were swollen and full of plague bacilli. No other organs were affected. The only other evidence that cats could and did suffer from plague came from Mauritius in the course of last year.

June 11th.

By the week ending June 16th there were remaining at Sydney suffering from plague 84 persons; 10 more patients were admitted and 15 were discharged; three died, leaving 76. The totals at this date read: Cases, 278; deaths, 98; discharged, 104; "contacts," 1559; "contacts" remaining, 100; and cases among "contacts," seven. Included among the above are cases among the Chinese, of whom 10 have been attacked, with eight deaths. All the other patients were whites.

No reason at all has appeared for supposing either that the cases recorded during previous weeks have not included practically all cases which have occurred, or consequently that the recorded cases were accompanied by a proportion of the ambulant cases usually observed or assumed during epidemics elsewhere. Recently, however, two or three such cases have been encountered. Thus a case which turned out to be plague having been reported by a medical man it was ascertained during inquiry that the patient's father had fallen ill just a week earlier. He had stayed from work for one or two days but had not thought it worth while to consult a doctor, yet he had an inguinal bubo of small dimensions and had had other symptoms which rendered it quite easy to give a confident diagnosis of plague. In another case, which came to light incidentally, the patient had never given up work; he also had been ill about a week and had a slight bubo. Both of these cases, which were promptly isolated at the plague hospital, would have been overlooked but for circumstances quite unconnected with the illnesses.

The second series of public inoculations yielded in all not more than 2500 inoculated in the course of more than a month, and has consequently been closed. Prophylactic serum is now being distributed to medical men; the demand is small and as such diffusion of it has practically no bearing on its use to prevent or abate an epidemic this need not be regretted. At all events, such preventive use of it has been made as the public would allow.

June 19th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Birmingham and Midland Eye Hospital.

THE annual meeting of the governors of this hospital was held on July 20th, when the seventieth annual report was read. In this it was stated that the extensive and necessary sanitary arrangements of the hospital had been completed, much to the comfort and well-being of the institution. The annual subscriptions amounted to £3716, and the donations to £792 11*s*. The total payments for the year amounted to £7204, but of this no less than £1429 had been expended upon repairs, including the sanitary alterations alluded to. The total number of patients were: in-patients admitted with ticket 589, without ticket 125; out-patients admitted with ticket 17,920, without ticket 9913. The medical report showed that 788 operations had been performed upon in-patients, 315 of which were for the removal of cataract or capsule, of which only three were unsuccessful. Iridectomy was done in 176 cases, and 93 eyes had to be removed. The number of operations on out-patients was 504, including 77 for the cure of squint and 293 for the removal of tumours from the eyelids. The committee expressed their satisfaction at the increased facilities for the accommodation of the nurses and servants. The question of affording aid to the children of the elementary schools who are known to want some sort of mechanical assistance to their eyesight was a subject which had engaged the attention of the committee, the chairman stating that no practical plan had at present been settled, the matter being beyond the power of the staff to deal adequately with such demands as would be made upon them from this source.

University of Birmingham.

The munificent donation of £50,000 from Sir James Chance comes as a welcome addition to the amount required to complete the endowment fund, which is stated to be £250,000. Equally generous is the gift of land from Lord Calthorpe and his son which is valued at £20,000. The new university has been fortunate in the friendship of those who have made large donations. Mr. Andrew Carnegie gave £50,000, and an anonymous donor a similar sum. The total amount promised in land and money reaches about £400,000, of which amount one half has been furnished by six donors. This is an encouraging example, yet there are still numbers who might swell the total by combined efforts in the cause of this valuable scheme in this great industrial centre.

Misleading Statistics.

It is a saying attributed to Sydney Smith that there is nothing so fallacious as figures except facts. The truth of the first part of the proposition is illustrated by the weekly return of the medical officer of health one week being 19·2 per 1000, while in the previous week it was only 15·6. It seems that the statistics from the workhouse had not been included in the latter return. It was stated in explanation at a meeting of the guardians that their returns were made

to the registrar's office and that the blame was not to be attributed to them. The entanglement of red tape appears to have come in as an element of error, and it is to be hoped that some arrangement between the respective authorities will cause some adjustment which will make these returns reliable as authoritative statements from the proper quarter.

July 24.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Manchester Sewage Case.

MR. YATES, Q.C., the stipendiary magistrate, delivered judgment on July 11th in the case of the Mersey and Irwell Joint Committee against the unhappy Manchester Corporation, which for a long time past has been in the condition, so far as the sewage question goes, of living between the hammer and the anvil, or, as some would have it, between the devil and the deep sea. It would be invidious to distinguish in the latter simile, but the Local Government Board, stolid and immoveable, may represent the anvil, while the Joint Committee hammers vigorously and repeatedly, the corporation having a bad time of it as it lies between the two. The corporation has a scheme believed to be efficient which the Local Government Board does not sanction. Meanwhile, pollution goes on to a disgraceful extent so that the Joint Committee prosecutes the corporation. As the magistrate said: "The difficulty really is that a proportion of the corporation do not realise the absolute necessity of doing at once what alone the Local Government Board will sanction, and do not realise the great injury they are doing day by day to those below their outfall." The Board insists on the purchase of land for filtration; the corporation does not want to buy land for that purpose nor does it go on with its own bacterial scheme, and so this filthy sewage flows into the Ship Canal and poisons the air for miles along its course, but it is said that plans and specifications are being prepared and that the whole question will be considered in September, and for that reason the magistrate did not "impose penalties for all the days referred to in the summons, but considering that this is the second occasion on which we have had to impose penalties we think that they must be increased, and we therefore impose a penalty of £50 in respect of each of five of the days (amounting to £250 and costs). We ought to add that if nothing is decided in September we shall have no option but to impose penalties, if asked to do so, *de die in diem*." If the hot weather continues, as it may, for the next two months the condition of the Ship Canal will be better imagined than endured.

The Extinction of Rabies.

It appears that the Board of Agriculture has now no muzzling orders in force. In 1895 as many as 672 cases of rabies were reported, but they have gradually decreased till last year when there were nine. The county of Lancaster suffered specially, having nearly a fifth of the total number of outbreaks. There were only five cases in 1898 and none since, so that we may hope to have done with the disease unless there is re-importation. The restrictions as to the movements of dogs into and out of the country seem in some cases unnecessary and pedantic, but it is as well to err on the side of caution and safety even at the cost of occasional private inconvenience and annoyance.

Glass in the Streets.

It is not very often that one finds public attention roused to one of the dangers of our streets and roads, that of broken glass; yet it has been recognised as a danger certainly since 1844, when an Act of Parliament gave magistrates power to impose a fine of 40*s*. for throwing broken glass into the streets. It is well, therefore, that the attention of the Manchester Watch Committee was drawn on July 12th to this "idle and senseless practice" by an influential deputation. The representative of the Royal Society for the Prevention of Cruelty to Animals spoke of the injuries to horses and other animals through broken glass. The Manchester and District Cycle Traders' Association, the Tram-owners' Association, the Mineral Waters Manufacturers, the Cyclists' Touring Club, the National Cyclists' Union, the Motor Car Club, the cycle employés of the Post Office, and other organisations were represented and concurred in the appeal to the committee. The numbers interested in this matter are very great. There are said to be 25,000 cyclists in the city whose tyres are endangered, as well as the numerous owners of rubber-tyred vehicles of all descriptions. The deputy-chairman of the committee told the deputation that there had been two prosecutions in the previous week, pointed out the great difficulty the police had in detecting offenders, and invited the coöperation of the general public. The throwing about and breaking of bottles is one of the bad habits of the British tripping public when holiday-making and is a great and dangerous nuisance in the country and the seaside. The education of the day has not done much as yet to soften manners and render them less brutish. This, however, does not come within the scope of the new code.

July 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Public Health of Dublin.

THERE has as yet been no practical outcome of the recommendations of the Viceregal Public Health Committee, but it is satisfactory to note that there has been nevertheless a steady and considerable reduction in the death-rate of the city extending now over many weeks. This is all the more important inasmuch as the city is already crowded with tourists, while an entirely unprecedented number of visitors are expected over next year to follow in the footsteps of Her Majesty the Queen.

The Dublin Boundaries Bill.

The judgment of the joint committee of both Houses as regards the Dublin Boundaries Bill was made public on July 19th. In connexion with the health of Dublin it is satisfactory to note the unanimous decision of the committee that it would be better to have the treatment of the sewage and drainage of the city and townships under the same administrative control. The recommendation is to appoint a joint drainage board for the city, Rathmines, and Pembroke representing the corporation and the two urban councils and to distribute over the entire area the past and future burdens of both systems of drainage. From the reply obtained from Mr. Balfour quite recently, in answer to a question put by Mr. T. Healy, M.P., this proposal of the committee will probably soon take legislative shape. In this connexion the corporation have scored a distinct success, for they have secured the condemnation of the outfall advised by the townships, while both Pembroke and Rathmines will eventually be forced to pay their share of the main drainage scheme.

Unqualified Midwives.

An inquest on a case of very great importance, especially at a time like the present when there is such a discussion in reference to midwives, was held on July 17th. It would appear that a married woman of the poorer classes, aged 34 years, died at her residence in a working-class district of Belfast on July 10th from post-partum hæmorrhage, having been previously confined of twins, one of whom was still-born. She had been attended by an unqualified "handy-woman" who, in her evidence, said that she had been practising midwifery for 20 years and had attended the deceased at six different confinements. A certified nurse who was called in found the woman (the children having been previously born) in a dying state. The confinement was in the evening and the "handy woman" said that on the next morning and afternoon she advised that a medical man should be sent for. The certified midwife swore that had she attended the woman in the morning and had seen her condition, as deposed by the "handy woman," she would have considered it her duty to have sent for a medical man. Dr. R. Munn said that death was due to post-partum hæmorrhage. He believed that a proper midwife would not have hesitated on insisting that a medical man should be sent for. The coroner, in summing up, said it was a terrible thing that the lives of people should be sacrificed by persons presuming to act as skilled nurses. If proper medical help had been procured both the mother's and the child's life might have been saved. The jury found that in the case of the mother death was due to hæmorrhage, and they considered that the woman who attended her did not bring about the death by want of skill or attention to her duties. The coroner said that all the jury had violated their oaths by arriving at a verdict contrary to the evidence and in the very teeth of the evidence. The foreman

protested against this allegation. In the case of the child the jury found that it was stillborn. The case is a most unsatisfactory one. On the one hand, those who really knew medically the circumstances of the case said that a medical man should have been called in. On the other hand, a lay jury said the "handy woman" was not at fault in neglecting to summon such advice. The whole case, by lifting the curtain, gives us an idea how the poor are still liable to be attended by the most ignorant women who have had no training; and it is a strong object-lesson in favour of preventing any of the so-called "handy women" being allowed charge of such cases. The better trained a nurse is the more quickly will she recognise that the gravity of the case demands that she should summon a medical man to her assistance.

The Typhoid Fever Epidemic at Belfast.

During the week preceding July 14th it appears that 34 cases of typhoid fever have been notified as compared with 41 in the corresponding one of the previous year. The death-rate from the principal zymotic diseases was 1·6, the death-rate from all causes being 15·7.

The Royal Victoria Hospital, Belfast.

It is said to be probable that the foundation-stone of the New Royal Victoria Hospital will be laid in September by the Prince and Princess of Wales when they visit Ireland.

Disastrous Shipping Accident in Belfast Lough.

On Saturday afternoon, July 21st, in a fog in Belfast Lough, two Scotch steamers, the one full of excursionists returning home from the North of Ireland to Glasgow, the other returning comparatively empty from Scotland, came in collision. The one vessel struck the other with a sliding blow, her anchor scraping along the side of the other and occasioning terrible injuries to the excursionists lining the rail. The excursion steamer returned to Belfast when the injured were removed by the admirable ambulance system (three vehicles were constantly employed) of the city to the Royal Victoria Hospital, where the resident and visiting staff (hurriedly summoned by telephone and messengers) had a very busy evening and night. It is said that five people, owing to the collision, have been killed; 21 are retained in hospital, and an immense number have been treated as extern patients. Not since the terrible railway accident at Portadown have the Royal Hospital staff had to cope so suddenly with such a serious surgical state of affairs. The company owning the steamers, the injured, and their friends have expressed their profound thanks to the hospital authorities and to the fire brigade for the splendid ambulance arrangements. From a surgical point of view there was a large number of injuries to the lower extremities (many of them compound fractures), some head cases, and a special feature was the unusual amount of shock present.

Dispensary Medical Officers and their Holidays.

So far the Local Government Board has made no order for the guidance of the dispensary committees on this much-discussed question and as a result the medical officers are being treated very badly. Here is the latest example. At the Downpatrick Board of Guardians Mr. D. S. Browne, dispensary medical officer of Portaferry, applied for three weeks' leave of absence, nominating Mr. V. P. Tighe of Dublin as his substitute. The guardians, however, agreed to allow him only a fortnight, congratulating themselves on their power to determine the duration of the medical officer's holiday pursuant to the late judgment in the Court of Queen's Bench. It is a great pity, after the statement of the Chief Secretary of Ireland in the House of Commons, that the Local Government Board delays so long in settling the matter. It is certainly not a sign of strength on their part.

The Annual Reports of the Resident Medical Superintendents of the Cork and Kerry District Lunatic Asylums

From the above reports it appears that the number of inmates in the Cork Asylum has increased by 36 and in the Killarney Institution by 22. In the Cork Asylum there are 1496 inmates, which is 239 over the standard limit; while in the Killarney Asylum there is still a small margin of accommodation available as the number of patients was 526 and the number for which there is accommodation is 683. In his report Dr. Woods, the resident medical superintendent of the Cork Asylum, makes the following instructive observations on the causes of insanity: "A further explanation for the steady increase in numbers must, I think, be set down to heredity. In many of my annual reports for the past 25 years I have laid stress on this fact, but some things cannot be said too often, and as the composition of asylum boards has within the last year so materially changed I think no harm can be done by again referring to the matter. Emigration tends to remove the fittest, those best able to withstand the battle of life, from our midst, leaving at home the delicate, the neurotic, and many liable to transmit to posterity the seeds of disease; the result is that at least 35 per cent. of cases of insanity in this country are directly traceable to heredity."

July 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Instructions for Troops going to China.

LAST week I mentioned the circular issued by the Minister of Marine giving instructions as regards principles of hygiene to the troops under orders for China. The circular points out that the chief points noticeable from a hygienic point of view in that portion of Northern China which lies between Tien-Tsin and Peking are the great extremes of heat and cold and the abominable quality of the water. Drinking-water in China, says the circular, is of very bad quality and the Chinese hardly ever drink it pure but substitute tea. In ships of the French navy serving in Chinese waters distilled water has been for many years exclusively used and thanks to this custom the health of the companies of French ships has been maintained in good condition under the most adverse circumstances. For an expeditionary corps operating in these parts the question of how to obtain a pure supply of drinking-water is very serious. Troops on the march cannot be supplied either with distilled water or with that sterilised in a special apparatus, for this latter is only available in hospitals and other permanent establishments. The most that can be done is to boil the water and even this measure in the circumstances under which an expeditionary force works is difficult to carry out. However, the ordinary drink of the Chinese is tea and therefore it is necessary to keep ones eyes open for this drink which is the common drink of the country and which has the additional advantage of being cheap and sustaining. On the march use should be made of the pocket filters made upon the Lapeyière system with potassium permanganate. These filters have the advantage of destroying large numbers of noxious germs from water, and several of these appliances have been given out to the troops. Wells, which in China are always contaminated, can be cheaply and easily disinfected by the permanganates either of potassium or of calcium. From five to 10 grammes of permanganate of potassium are enough for a litre of water. Coincidently with the permanganate the use of a mixture of one part of powdered charcoal to three parts of fine sand is recommended. Soldiers should by all means avoid the use of alcohol which is so widespread in China. In the north of China they distil a spirit from *sorghum* (cane) which is of deeper colour in proportion to its inferiority. It is sold at from 60 to 100 sapeks per litre, that is to say, at from 30 to 50 centimes. Spirits are also distilled from sundry kinds of grain which are most impure and dangerous to health. Butcher's meat can be obtained in plenty, as well as poultry, game, fresh vegetables, and fruit of excellent quality. As a general rule the use of pork should be eschewed, the pig being frequently affected with cysticercus and trichinosis. Fresh-water fish is always bad and tastes of mud, as do the fresh-water shrimps and crayfish owing to the dirty condition of the watercourses, and all these had better be avoided. During the hot season malaria is very prevalent in the Pei-Ho basin and the precautions laid down for troops operating in malarious countries must be strictly observed. For any special means to be adopted the commanding officer must confer with the principal medical officer. Heat-stroke and sun-stroke are common in July and August and congestions of the liver are frequent during the summer. After malaria, however, the dominating pathological factor of the summer in China is diarrhœa. Every case of diarrhœa, however slight, should be treated at once, for epidemics of cholera are frequent in China, and any diarrhœa may be a starting point for an attack of cholera if cholera vibrios happen to be present in the intestine. During the winter respiratory affections are common, in

addition to rheumatism, diphtheria, and typhus fever of a petechial type. Small-pox is practically endemic, vaccination being almost unknown outside centres having a resident European population. Revaccination should therefore be carried out throughout the expeditionary corps. For the hot season troops should be supplied with cholera belts, mackintosh sheets, and mosquito curtains. For the bitter winter of Northern China troops should be supplied with additional warm clothing and the commanding officer should be instructed to allow both officers and men to wear furs, which can be obtained in the country at a cheap rate.

Medicine and the Theatre.

Among the numerous congresses which are at present being held in Paris and of which many deal with questions never before discussed, as is only fitting at the dawn of a new century, is one which, although at first sight it would appear to be far removed from having any medical interest has yet put down on its programme a series of questions of the deepest interest to medical men. I allude to the Congress on Theatrical Art which will sit from July 27th to 31st. Here will be discussed the following questions which are most interesting from a hygienic point of view: the mode of nominations and status of the medical men attached to subsidised theatres; the best method of organising the medical department and its relations with the Prefect of Police; the statistics of accidents occurring in the course of representations or rehearsals; the inspection and upkeep of emergency chests (*boîtes de secours*); medical aid to the staff at their homes; reports and opinions; the unhealthiness of rooms, the stage, and the dressing-rooms; warming and ventilation; the representation and the powers of medical men on the governing body of theatres; consideration of the arrangements which could be carried out in the building of the next popular theatre. A report will be laid before the Congress and a committee appointed which will sit until some practical conclusion has been arrived at. M. Lefeuve is in charge of the report and those interested in the matter are requested to communicate with him. Another congress dealing more especially with music will consider the hygiene of singers and instrumentalists. This congress will begin in November and will be assisted by the advice of the most experienced artists and professors.

July 24th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

An Alleged Hospital Scandal.

A CONSIDERABLE sensation was caused not long ago by an article published in the *Medicinische Reform* drawing attention to a paper in the *Archiv für Klinische Medicin* wherein Dr. Strubell, an assistant in the Jena Medical Clinic, had described certain methods used by him in the treatment of a case of diabetes insipidus. Dr. Strubell endeavoured to combat the disease by limiting the daily quantity of drinking water to a very small amount, the effect being that the patient suffered very much from thirst and procured water and other beverages secretly. Dr. Strubell accordingly locked the man in a room with barred windows and kept the key himself. The sufferings of the patient were described in an unfeeling manner by Dr. Strubell who mentioned that the man was found to have drunk from a waste pipe near the window; he was so tormented by thirst that he drank dirty water out of the washing-tub and even his own urine. Symptoms of cardiac failure appeared during the treatment, and eventually the patient had to be discharged. In the above-mentioned article printed in the *Medicinische Reform* Dr. Strubell's proceedings were very severely blamed, especially because the tenor of his communication might induce readers to believe that the patient was subjected to this treatment not for curative but for experimental purposes. The editor of the *Medicinische Reform* stated that the medical press and the medical profession disapproved of such methods, and he hoped that the medical profession might be able to come to an authoritative decision on the matter without the intervention of non-medical journals. Unfortunately, the expectations of the *Medicinische Reform* were not realised, Dr. Strubell's article being at a later date severely blamed by several non-medical journals of different political views. For several weeks the columns of the newspapers were filled with articles and letters on this question, Professor Neisser's alleged misdemeanours being compared with the above case, and of course unqualified practitioners, homœopaths, and others joined in the general chorus of blame which was raised against the whole medical profession. The chief physician of the Jena Medical Clinic, Professor Stintzing, then declared himself responsible for everything that had happened in this clinic. He said that notwithstanding the malicious suggestions of certain periodicals the facts were that the treatment had been tried for curative purposes, that the patient had been informed of some inconveniences he might experience, that he nevertheless consented to be treated in this way, that he was at liberty to leave the hospital whenever he chose but that he remained there for two months and afterwards returned of his own accord, that the events described by Dr. Strubell happened three years ago, and that the patient (who died in 1899) had up to the time of his death always been grateful to the physicians of the clinic. Professor Stintzing admitted that Dr. Strubell's descriptions might lead his readers to form erroneous opinions, but the charges of inhumanity towards the patients made against the physicians of that clinic were quite unfounded. The respectable periodicals acknowledge the importance of Professor Stintzing's letters, but it is to be feared that Dr. Strubell's case will continue to be the object of severe criticism in some newspapers and at public meetings of that section of the public who are only too glad to have an opportunity of extolling the so-called "popular medicine," homœopathy, and other unorthodox systems.

The Expeditionary Force for China.

Great efforts are being made in order that the troops ordered to China may be provided with a sufficient staff of surgeons and nurses and with an adequate supply of medical stores. Apart from the official organisations afforded by the medical departments of the Army and Navy the German Red Cross Association hastened to join the military authorities in working for the benefit of the wounded soldiers. Trained male attendants and nurses will be sent to the scene of war in China with everything necessary to establish Red Cross hospitals. The direction of the hospitals will be confided to Dr. Küttner of the Tübingen Surgical Clinic, who certainly has become one of the most experienced military surgeons in Europe. Dr. Küttner, who has just returned from Africa, will start at once for China and this will be the third war in which he has served, the previous ones being: (1) that between Turkey and Greece in which he was attached to the great military hospital at Constantinople; and (2) the Transvaal war where he was at the head of the German ambulance with the Boers at Jacobsdaal. A great many surgeons and nurses have applied to the Committee of the Red Cross Association seeking to be enrolled on its staff.

The German Practitioners' Association.

The annual meeting of the German Practitioners' Association (Deutscher Aerztetag) took place on June 22nd and 23rd at Freiburg in Baden, the late president, Dr. Aub of Munich, being replaced in the chair by the vice-president, Professor Löbker of Bochum. The association at present has 291 branches and 16,583 members, and of these 183 branches, including 14,790 members, were represented. The first subject of discussion consisted of questions relative to death certification, and the association adopted a motion of Dr. Becher of Berlin that every case of death ought to be certified by a qualified medical practitioner. The second subject of discussion was the relation of the first-aid and ambulance association to the medical profession. The Practitioners' Association recommended that the first-aid service should be in connexion with the hospitals and that the control should be vested exclusively in medical men. This part of the business was followed by an animated discussion on the conditions under which German medical men carry on practice abroad. Dr. Joachim of Berlin recommended that the association should establish an office for the purpose of giving information to German practitioners intending to go abroad. The assistance of the consular department in this matter had already been asked for by the Berlin branches of the association. One of the Hamburg delegates was of opinion that the office ought to be in that city and that it ought to have control over the appointment of medical officers to merchant vessels both steamers and sailing ships. The association agreed with this proposal. Other subjects of discussion related to fees in club practice, to insurance

companies, to unqualified practitioners, &c. Dr. Löbker of Bochum was elected president.

Hints to Contributors to the Medical Press.

Professor Virchow, the editor of the *Archiv für Pathologische Anatomie*, has addressed some words of counsel to the contributors to that periodical and to medical authors generally, explaining several points which it is desirable that writers for the medical press should always keep in mind. It would be difficult to find a higher authority on this subject than Professor Virchow, the patriarch of the savants and editors of Germany. His remarks are not intended for authors of books, who are at liberty to write as they like; they have been published exclusively for he benefit of contributors to medical weekly, monthly, or quarterly journals. He says that it is one of the elementary principles of journalism that the successive numbers of a journal must be issued at a certain time and in a certain size. Contributors must therefore endeavour to write concisely, taking up as little space as possible and avoiding all superfluous matter. Descriptions of cases, experiments, and necropsies when sent to editors for publication are often so voluminous that it is impossible to use them without serious inconvenience. The publications of series of cases, &c., in the form of tables is a great annoyance both for the editor, the printer, and the readers. Controversies as to priority are often offensive in style and lacking in the courtesy due to professional brethren. Finally, contributors ought to abandon the custom of quoting long passages from other authors with the object only of showing their knowledge of medical literature.

July 23rd.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Sanatorium for Consumptives.

THE first yearly report for 1899 of the Canton of Zürich's Sanatorium for Consumptives offers several points of interest. This sanatorium is situated at Wald at an altitude of 907 metres. The heliograph marked in the four winter months 465 hours of sunshine (Davos 445, Zürich 332). There are 88 beds, of which an average of 72 were continually occupied. 319 patients were admitted and remained an average of 104 days, 36·4 per cent. belonging to the first stage (Dr. Turban's scale), 26·3 to the second stage, and 37·3 to the third stage. Out of 76 patients in the first stage 48 were cured and 22 were eminently better. Of those in the second stage (55) none were cured and 35 were eminently better. Of those in the third stage (78) only 13 were eminently improved. These statistics go far to prove that only cases in the first and also the beginning of the second stage promise good results.

Dr. Tez's Typhoid Extract.

This has been tried at the University Hospital, Zürich, in eight cases, which were all chosen among the worst cases in the first or second week of the disease. After injections they rapidly improved and were free from fever within four days. In one other very severe case which had lasted three weeks and where the temperatures ran up to from 103° to 105° F. continuously the injections of this serum were also crowned with success in seven days, an ensuing relapse being also treated successfully. Professor Eichhorst can thus recommend a trial in all cases severe from the onset or even later. No deleterious effects were observed.

Tuberculin Injections for Diagnostic Purposes.

Though not an advocate of tuberculin injections for therapeutic purposes Professor Eichhorst of Zürich strongly recommends them to secure diagnosis in doubtful cases with pulmonary and other symptoms. The injection of one milligramme of Koch's old tuberculin must be followed by a feverish reaction to secure a positive diagnosis of tuberculosis. Should no reaction follow, three and eventually five milligrammes can be injected at intervals of from two to three days. A case of morbus Addisonii and a case of pseudo-leukæmia were thus diagnosed as based on tuberculosis.

Zürich, July 21st.

RUSSIA.

(FROM A CORRESPONDENT.)

The Outbreaks of Plague in the Kirghiz Steppe.

IN February last I communicated to your columns[1] a short account of an epidemic of plague which had occurred in two Kirghiz settlements in southern Russia. No further details in regard to this isolated outbreak have, I believe, as yet been published. A full account of the epidemic from the pen of an eye-witness is therefore particularly welcome. Such an account is furnished by Dr. Arustamof in the pages of the *Vratch* (1900, No. 15). The article is too long to quote in full, but the following is a short summary of the principal facts which it contains. The scene of the outbreak was the Caspian Sea portion of the Kirghiz steppe in the eastern part of the government of Astrakhan. This steppe extends from about 45° to 50° N. latitude, and from about 47° to 51° east longitude (from Greenwich). It is about 300 versts long and 400 versts broad, and contains approximately 300,000 inhabitants. The greater parts of the steppe is composed of sand, forming irregular mounds and almost devoid of vegetation. To the south the sand gives place to yellow sunken deposits of salt, entirely devoid of vegetation. The Kirghiz inhabitants live a nomad life, in summer in tents, in winter in *zemlianki* or earth huts. On the shore of the Caspian Sea and on the islands near it the population is somewhat denser. It was on one of these islands that plague first made its appearance in October last. On the 25th or 26th of that month the daughter of a *moullah* living on the island of Irsalou-Aral, belonging to the Kirghiz horde, fell ill with symptoms resembling those of plague How she contracted the disease is unknown. The Kirghiz are fanatical Mussulmans and often visit Mecca (where plague, it will be remembered, was present last year), but it seems that they are very loth to give any information to a non-believer as to whether they have or have not been to the Holy Places. Irsalou-Aral (*aral* means a mound) is a small island on the Caspian and it contained at the time of the outbreak a population of 52 persons. On October 25th or 26th, as just stated, the *moullah's* daughter fell ill and she died five days later; on the 26th his son, aged 15 years, fell ill in the steppes, 12 versts away, and died on Nov. 3rd. Other cases followed, and on Nov. 26th the *moullah* himself fell ill but recovered. In all, 25 persons out of the total population of 52 were attacked by the disease and as many as 22 died. In the meantime the infection spread from this island to those of Kishkine-Aral and Kine-Aral, the two islands which were alone mentioned in the accounts of the outbreak first published. They are separated from each other by a strip of water under 100 yards in width, and they lie some 35 versts (or 24 miles) away from Irsalou-Aral. The first case in Kine-Aral, which occurred on Nov. 13th, was that of a woman, the sister of two patients who had died in Irsalou-Aral. It is not definitely stated that the woman had visited her relatives there, but it is to be supposed that some communication between them had taken place. On the same day the woman's son, a boy, aged five years, was attacked, and both died two days later. The disease appeared about the same time in Kishkine-Aral, and in the two islands as many as 39 deaths occurred out of a total population of only 65. Whole families were swept away and the unfortunate survivors became panic-stricken. They were unable, however, either to fly or to get help from the mainland. Just as the outbreak was at its worst a severe storm broke over the northern end of the Caspian Sea; the ice which was beginning to form was broken up, and it was impossible to cross to the mainland either by boat or on foot across the ice. It appears probable that, while this condemned the affected islanders to suffer and die without help, it also prevented the disease from spreading to other islands or to the mainland. It was not until Nov. 28th that news of the outbreak reached the ears of the sole *feldscher* in the neighbourhood—the *feldscher* attached to certain fishing industries—who reported it to the authorities. A medical man reached the scene of the epidemic on Dec. 4th and measures were at once put into action to deal with the outbreak. Later others visited the island and on Dec. 11th the author of the article from which this account of the epidemic is taken himself attempted to cross to the island of Irsalou-Aral.

[1] THE LANCET, Feb. 3rd, 1900, p. 350.

He failed, however, on his first attempt; the ice was as yet too weak to drive over, and on trying to do so the horse and cart fell through into the water, immersing him, with his baggage and supply of drugs which he was taking with him. A second attempt at another part of the ice was equally unsuccessful. On the following day a third attempt was made, but only with the same results—a fresh wetting for himself and all his supplies. On the third day, however, he succeeded in getting across in a boat. At that time 21 out of the small population of the island were already dead and one was still ill. The first 13 bodies had been buried, but eight others remained unburied, the survivors dreading to touch them.

In each of the islands the surviving healthy persons were given a bath in a disinfectant, were clothed in entirely new clothes, and were removed to houses or tents where no case of the disease had yet occurred. The infected huts or tents with their contents and with the unburied bodies of those who had died were burned down. A cordon of mounted Kirghiz was drawn round the infected settlements. These measures seem to have succeeded, or at least to have aided in checking the course of the epidemic. The outbreaks, in fact, practically ceased in all the islands from the time that these measures were put into force. The other conditions were practically favourable at the time for the extinction of an epidemic. The extreme isolation of the communities affected, the smallness of their numbers, and the onset of extremely cold weather were all, no doubt, conducive to the cessation of the further spread of a disease such as plague. But there can be little doubt that the measures above briefly enumerated were mainly instrumental in stopping the ravages of the disease. On Dec. 16th the outbreaks were completely over. The survivors were housed in uninfected huts. All inside the contaminated zone, including medical men, feldschers, police officials, and others, were provided with new clothes, and their old ones were burnt or disinfected. A number of surrounding villages, over a large area, and containing a population of over 10,000 persons, were examined for traces of any suspicious disease, and later the islands were visited by Professor Levin, Professor Raptchevski, and Professor Vinogradof on behalf of the Russian Plague Commission, from whom a report should be forthcoming shortly. Although no bacteriological evidence of the nature of the disease in these outbreaks has as yet been published there seems no reason to doubt that it was the plague. The symptoms were principally those of fever, headache, vomiting, extreme prostration, spitting of blood, and death in two or three days. None of the patients seem to have presented buboes, and it is reasonable to suppose that the outbreak was one of plague in its pneumonic form. In this respect, as well as in regard to its local intensity and fatality, the outbreaks are closely analogous to that which occurred at Kolobovka on the Lower Volga in the summer of 1899. In that, as in the outbreaks now under consideration, no trace of the source of the infection could be discovered.

July 23rd.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

A Bureau of Public Health for the Dominion.

DR. RODDICK, M.P., is taking an active interest in the direction of having established a central board of health for the entire Dominion. Speaking on the subject recently in the Canadian House of Commons he pointed out the importance of concentrating all subjects relating to sanitary affairs, marine quarantine, the sanitation of Indian reserves, leper asylums, vital statistics, the sanitary portion of the census, the protection of waterways, sanitary measures in unorganised territories, the protection of public health against the invasion of tuberculosis, and the importation of unhealthy articles of food and freight, such as rags. The question of sanitary police he thought a particularly important one at the present time. The Dominion authorities should have such men now on the shores of British Columbia to guard against the introduction of that loathsome disease, the bubonic plague. Besides, they had need of a bacteriological laboratory, for at present they had to depend upon the United States, England, and even sometimes upon Japan. He thought they should have in their own country a laboratory under the charge of a capable man, in which should be carried on the manufacture of prophylactic serums of various kinds. Recently he had attended a medical convention in the United States where a professional gentleman had read a paper on leprosy who stated that it was his purpose to proceed to Ottawa to make a study of the subject in the laboratory there. Dr. Roddick had to inform him that such an institution did not exist. Canada was a long way behind in this respect and he thought the Government might well look carefully into the matter during recess, which the Minister of Agriculture promised to do, so that very likely there will be a report to deal with at the next assembling of the House. The Government also should have medical men in the great ports of Europe and the Orient who should carefully examine intending emigrants and see that the ships are properly equipped for the sanitary care of those on board. The formation of a Dominion Medical Council, Dr. Roddick believes, will go much toward securing the creation of a department of public health in the Government of the country.

The Extent of Leprosy in Canada.

The Hon. the Minister of Agriculture in the Dominion Parliament, in answer to questions regarding the extent of leprosy in the Dominion, stated recently in the House of Commons that there were 19 lepers in the lazaretto at Tracadie, New Brunswick, 14 being from that province, one from Prince Edward Island, three from Manitoba (the disease having been contracted by these in Iceland), and one from the province of Nova Scotia. One of the Manitoba cases had died in January, 1897, and another in July of the same year. The Minister also stated that he had been informed early in the autumn of 1897 that there were six lepers in the lazaretto on Darcy Island, British Columbia, all of whom were Chinese. Since that year these have not been under the control of the Dominion Government but are in the immediate hands of the Government of the province of British Columbia.

Tinea Favosa Quarantine.

In view of the fact that the quarantine officers of New York and other ocean ports along the Atlantic seaboard are excluding from landing immigrants the subjects of this disease it becomes of some importance to the people of Canada, more particularly those down by the sea in the maritime provinces of Nova Scotia and New Brunswick. Last spring it was stated that several of the rejected ones had found shelter in these provinces and on Cape Breton Island, but although a diligent and persistent search was prosecuted they could not be located. This disease is not as yet considered by the immigration authorities of Canada as a sufficient cause for exclusion or even quarantine; but the recent action of the United States Government, combined with the fact of the continual growth of St. John, N.B., as a port of entry for transatlantic passengers, makes favus one of interest to the profession as well as to the general public in that locality, which is bound to result in similar efforts being put forth to exclude the introduction of these diseased hordes into Canada. The disease seems to be very prevalent in New York and it is from this source when rejected and excluded that New Brunswick and Nova Scotia fear its introduction. Here and there a few isolated cases have been reported in Canada, one particularly interesting case having occurred in the Montreal General Hospital in which nearly the whole cutaneous system was involved.

The Ontario Medical Association.

The twentieth annual meeting of this association was held in Toronto on June 6th and 7th, under the presidency of Dr. Adam H. Wright of this city, Dr. Harold C. Parsons acting as secretary.—The first discussion was an interesting one upon the Use of Morphia in Puerperal Eclampsia, some adhering to and endorsing this method whilst others had found the bromide-chloral treatment superior and more effective.—Dr. Luke Teskey, Professor of Clinical Surgery in Trinity Medical College, read a valuable paper on Appendicitis. He classified this disease into three forms: catarrhal appendicitis, acute circumscribed appendicitis, and gangrenous appendicitis. He laid particular stress upon the chronic symptoms of indigestion and the progressive loss of body-weight in the first class of cases; he counselled operation in all these cases and thought that the recoveries ought to be 100 per cent. In the second class an important diagnostic point was the feeling of resistance which one always finds in local inflammatory processes; when that resistance was first felt that was the time for operation. In the third class an early operation

was the only hope for the patient.—Inter-provincial Medical Registration was a live topic for discussion. Dr. Roddick was present and addressed the meeting at some length on this subject. In his hands is intrusted the Bill to bring this question into practical effect. The meeting unanimously approved of the formation of a Dominion Medical Council.—Two Cases of the Total Removal of the Vas Deferens and Vesiculæ Seminales were reported, one by Dr. George A. Peters of the University of Toronto and the other by Dr. J. Alexander Hutchinson of the University of McGill.—Dr. Peters further gave a very interesting report of a case of Transplantation of the Ureters in the Rectum by Extra-peritoneal Method, for which he claims priority and originality. The little patient is now six years of age and can hold his urine in the rectum at night for eight hours and in the daytime for three hours. The boy had also been the subject of a procidentia recti which had been corrected.—The Adaptation of Patient to Climate in Cases of Phthisis was the subject of an interesting address by Dr. N. A. Powell of Toronto, who pointed out the advantages of the Muskoka region and the North West and Rocky Mountain regions for the subjects of this trouble.—Professor William Oldright of Toronto University showed an interesting case of Necrosis of the Skull in an old syphilitic, aged 56 years. It measured five inches either way in extent.—Numerous cases of Cancer of the Rectum were reported by Dr. E. E. King of Toronto, the illustrations by lantern slides adding greatly to the effect of the reports.—Observations upon Blood-pressure in Dogs were shown by means of lantern slides by Dr. R. D. Rudolf of Toronto.—Dr. H. B. Anderson, Professor of Pathology in Trinity Medical College, read a paper on Acute Rheumatism and reported finding Achlame's bacillus in one case, the patient having died one week after being attacked. He thought the work of this investigator had not met with sufficient approval in England and America.—The subject of the Army Medical Arrangements for the War in South Africa was ably handled by Dr. J. T. Fotheringham and proved a very interesting feature of the meeting.—Dr. Angus Mackinnon, Guelph, Ontario, was elected President, and Dr. Parsons was re-elected secretary.

Toronto, July 7th.

Medical News.

UNIVERSITY OF LONDON.—At the intermediate examination in Medicine held in July the following candidates passed in the subjects indicated:—

EXAMINATION FOR HONOURS.

Anatomy.—First-class: Joseph Ebenezer Adams, St. Thomas's Hospital; M. A. M. Fitzmaurice-Kelly, St. Mary's Hospital; Charles Wesley Forsyth, Owens College; Harold Ashton Lyth (exhibition and gold medal), University College; Robert Pugh Rowlands (gold medal), Guy's Hospital; and Arthur Rendle Short, B.Sc., University College, Bristol. Third-class: Arthur Hamilton, St. Bartholomew's Hospital; Constance Brodribb Slater, London School of Medicine and Royal Free Hospital; and John Harry Watson, University College, Liverpool, and King's College.

Physiology and Histology.—First-class: Percy Reginald Bolus (gold medal) and Edwin Henry Britton Milsom, Guy's Hospital; and Arthur Rendle Short, B.Sc. (exhibition and gold medal), University College, Bristol. Second-class: Helen Chambers, London School of Medicine and Royal Free Hospital; Herbert Ernest Corbin, B Sc., and M. A. M. Fitzmaurice-Kelly, St. Mary's Hospital; Ellis Gordon Goldie, Guy's Hospital; Harold Ashton Lyth, University College; and Constance Brodribb Slater, London School of Medicine and Royal Free Hospital. Third-class: D. Henriques De Souza, B.Sc., University College; Henry Ratcliff Kidner, St. Bartholomew's Hospital; Charles Ernest W. Lyth, University College, Sheffield; and Neville Ivens Spriggs, Guy's Hospital.

Organic Chemistry.—First-class: Herbert Ernest Corbin, B.Sc., (exhibition and gold medal), St. Mary's Hospital; and *Millais Culpin, London Hospital. Third-class: Percy Reginald Bolus and Edwin Henry Britton Milsom, Guy's Hospital.

Materia Medica and Pharmaceutical Chemistry.—First-class: Robert Pugh Rowland, Guy's Hospital; Arthur Rendle Short, B.Sc. (exhibition and gold medal), University College, Bristol; and †Constance Brodribb Slater, London School of Medicine and Royal Free Hospital. Second-class: Thomas Paul Baldwin, St. Bartholomew's Hospital; Henry Swarbrick Brown, Guy's Hospital; M. A. M. Fitzmaurice-Kelly, St. Mary's Hospital; and Christian Cathcart Robinson, St. Bartholomew's Hospital. Third-class: Stanley Bean Atkinson, B.Sc., St. Bartholomew's Hospital; Herbert Ernest Corbin, St. Mary's Hospital; and David Henriques De Souza, University College.

* Obtained number of marks qualifying for the exhibition.
† Obtained number of marks qualifying for the medal.

PASS LIST.

Entire Examination.

First Division.—John Braithwaite, Guy's Hospital; William Alfred Brend, B.Sc., King's College; George Herbert Brown, Owens College; Harold Benjamin Day and John Alexander Drake, King's College; Harold Cruickshank Lees, St. Mary's Hospital; Agnes Agatha Parson, London School of Medicine for Women; Rees Phillips, Middlesex Hospital; and David Lindley Sewell, Owens College.

Second Division.—Joseph Baird Albury, St. Mary's Hospital; Frederick Hugh Alexander, University College; Oliver Francis Haynes Atkey, King's College; George Ernest Aubrey, St. Bartholomew's Hospital; Anne Thompson Barnard, London School of Medicine and Birkbeck Institution; Mary Cecilia Bell and Ruth Levy Bensusan, London School of Medicine for Women; George Archibald Bosson, University College; William Frederick Box, Guy's Hospital; Sidney Arthur Boyd, Charing-cross Hospital; Walter Briggs, Owens College; Agnes Maud Brown, Queen Margaret College, Glasgow, and London School of Medicine; Gerald Lantsbery Bunting, Westminster Hospital and Birkbeck Institution; Joseph Burfield, St. Bartholomew's Hospital; John Hay Burgess, St. Mary's Hospital; Harold John De Brent, St. Thomas's Hospital; Henry De Vine, University College, Bristol; John Thomas D'Ewart, Owens College; Albert Davies Edwards, University College, Cardiff; Francis William Fawssett, Guy's Hospital; Arthur Frost Forster, St. Bartholomew's Hospital; John Gay French, St. Mary's Hospital; William Gillitt, Middlesex Hospital; Llewellyn Stanley H. Glanville and Philip William Hamond, Guy's Hospital; Thomas Henry Harker, St. Bartholomew's Hospital; Elizabeth Hill, London School of Medicine for Women; Ethel Florence Iredell, B.A., London School of Medicine and Royal Free Hospital; Smeeton Johnson, St. Mary's Hospital; Ivor Davenport Jones, Middlesex Hospital; William Ronald Kirkness, King's College; Reginald Larkin, Guy's Hospital; Alfred Lewthwaite and George Bartley McKean, University College; Lionel Henry Moiser, Guy's Hospital; Gilbert Phillips Moscrop, London Hospital and Alwyne Institution; Arthur Cyril Motta, St. Mary's Hospital; Frederick Cecil Robinson, Guy's Hospital; Dansey Smith, Middlesex Hospital; Mary Townsend, London School of Medicine for Women; Laura Sobey Veale and Edith Waine Turner Watts, London School of Medicine and Royal Free Hospital; Bernard Harry Wedd, Guy's Hospital; Eugene Christopher Whitehead, Westminster Hospital; and Hilda Kate Whittingham and Ivy Evelyn Woodward, London School of Medicine for Women.

Excluding Physiology.

First Division.—George Cuthbert Adeney, St. Thomas's Hospital; and Charles Derwent Pye-Smith and Ernest William Strange, Guy's Hospital.

Second Division.—Ernest William Charles Bradfield, St. Mary's Hospital; Desborough Brodie, St. George's Hospital; George Brooke Forbes Churchill, Guy's Hospital; Ruby Ellen Glanville, London School of Medicine for Women; Herbert Myer Goldstein, Guy's Hospital; Ida Margaret Guillaume, London School of Medicine for Women; Vernon Hetherington, St. George's Hospital; Beatrice Mary Kidd, London School of Medicine and Alwyne Institution; Alexander Manuel, St. George's Hospital; Wilfrid Ombler Meek, Owens College; Henry Richmond Minkley, St. Mary's Hospital; John Noel Sergeant, St. Thomas's Hospital; Herbert Bartlett Simpson and Malcolm William Stewart Smith, University College; James Batson Stephens, St. Mary's Hospital; R. Archibald Slater Sunderland, St. Bartholomew's Hospital; Louisa Graham Thacker and Henrietta Leila D. Williams, London School of Medicine for Women; Agnes Williamson, London School of Medicine and Royal Free Hospital; Frederick Robert Elliston Wright, St. Thomas's Hospital; and Walter Perceval Yetts, St. Bartholomew's Hospital and University of Edinburgh.

Physiology only.

Second Division.—Henry Edgar Barnes, St. Mary's Hospital; Frederick Alexander Beattie, Guy's Hospital; Alwyn Hewett Bradley, Mason University College; John Dell Bridger, Guy's Hospital and Alwyne Institution; Alexander Cameron, Middlesex Hospital; Daniel Cyril Evans, St. Bartholomew's Hospital; John Evans, Guy's Hospital; John William Fox, London Hospital; David Sydney Graves, Guy's Hospital; Helen Moore, London School of Medicine and King's College; Marie Louise Pethick, London School of Medicine and Royal Free Hospital; George Struan Robertson, Guy's Hospital; and Arthur Reginald Schofield and William Bartholomew Vaile, London Hospital.

N.B.—The foregoing lists, published for the convenience of candidates, are provisional only, and are not final until the reports of the examiners shall have been confirmed by the Senate.

SOCIETY OF APOTHECARIES OF LONDON.—In July the following candidates passed in the subjects indicated:—

Surgery.—H. C. Cooper, St. George's Hospital; H. S. Davies (Section II.), Michigan; C. J. E. Edmunds (Section I.), St. Thomas's Hospital; E. Evans (Sections I. and II.), Royal Free Hospital; J. S. Goodall (Sections I. and II.), Middlesex Hospital; T. B. Haig (Section II.), St. Bartholomew's Hospital; S. K. K. Haslam (Section I.), Royal Free Hospital; H. N. Horton (Section I.), Middlesex Hospital; J. Klein (Sections I. and II.), St. Mary's Hospital; R. Lamort, Bordeaux; R. A. Lyster, Birmingham; C. J. Marsh, University College Hospital. W. T. Meagher, Cork; R. E. Roberts (Sections I. and II.), St. Thomas's Hospital; F. Robinson (Sections I. and II.), Royal Free Hospital; E. F. Rose (Sections I. and II.), St. Bartholomew's Hospital; W. C. Stanham, London Hospital; M. H. Style (Sections I. and II.), Royal Free Hospital; C. H. St. M. W. Toke, St. George's Hospital; and E. Tyson, St. Bartholomew's Hospital.

Medicine.—P. J. R. Bucknill (Section I.), Manchester; F. P. Bush and C. W. Gibson, Guy's Hospital; J. S. Goodall (Section II.), Middlesex Hospital; T. B. Haig (Sections I. and II.), St. Bartholomew's Hospital; S. K. K. Haslam (Section I.) and D. E. Lockwood (Section I.), Royal Free Hospital; R. E. Roberts (Sections I. and II.), St Thomas's Hospital; F. Robinson (Sections I. and II.), Royal Free Hospital; J. Waters (Sections I. and II.), Middlesex Hospital; A. J. Watson (Section I.), St. Mary's Hospital; and H. F. Willington, Manchester.

Forensic Medicine.—F. P. Bush and C. W. Gibson, Guy's Hospital; T. B. Haig, St. Bartholomew's Hospital; R. E. Roberts, St. Thomas's Hospital; F. Robinson, Royal Free Hospital; J. Waters, Middlesex Hospital; and A. J. Watson, St. Mary's Hospital.

Midwifery.—C. H. G. Atkyns, Birmingham; R. V. Cowley, Edinburgh and St. Mary's Hospital; A. McC. Dallas, Guy's Hospital; and H. F. Willington, Manchester.

The diploma of the Society was granted to the following candidates entitling them to practise Medicine, Surgery, and Midwifery:—F. P. Bush, H. C. Cooper, A. McC. Dallas, H. S. A. Davies, E. Evans, J. S. Goodall, T. B. Haig, J. Klein, R. A. Lyster, W. T. Meagher, W. C. Stanham, M. H. Style, C. H. St. M. W. Toke, and E. Tyson.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred:—

Degree of Doctor of Medicine (M.D.).—Charles George Cowie, M.A., M.B., C.M., Ellon; William Stewart Geddie, M.B., C.M., Gympie, Queensland, Australia; Alexander Barclay Lyon, M.B., C.M., Hammersmith, London, W.; and Alex. Hendry Mackie,* M.A., M.B., C.M., Aberdeen.

Degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.) (Old Ordinances).—Alfred Alwyne Hingston, B.A., Clifton, Yorks.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch. B.) (New Ordinances).—Alexander Bisset, Aberdeen; William Fraser Bisset, Aberdeen; Allan James Craigen, Georgetown, Demerara; William Flett Croll, M.A., Aberdeen; Arthur Davidson, Dunnydeer, Insch, Aberdeenshire; James Andrew Sandilands Grant, M.A., Methlick, Aberdeenshire; Herbert Johnstone, Upholland, near Wigan; James Macfarlane, Aberdeen; Miss Myra Mackenzie, Aberdeen; Colin Forbes Marr, Ellon, Aberdeenshire; Herbert Playford Sheppard, Bedford; Henry William Martyn Strover, Tonbridge, Kent; Francis Henry Wessels, B.A., Claremont, near Cape Town, South Africa; James Wilson, Gardenstown, Banffshire; and Charles Melville Young, Highgate, London.

The John Murray Medal and Scholarship (awarded to the most distinguished graduate (M.B.) of 1900) and the Alexander Anderson Scholarship were awarded to Henry Fraser, M.B., Ch.B., Aberdeen.

Degree of Bachelor of Science (B.Sc.).—Charles Allan, Burnside, Fordyce; Robert Neal Rudmose Brown, Aberdeen; George Gall Esslemont, Ord of Cardno, Fraserburgh; Joseph Knox, Aberdeen (with special distinction in geology and chemistry); Alexander Christie Reid, M.A., Ellon; and John Wishart, Aberdeen.

Diploma in Public Health.—David Hunter Aioslie, M.B. Aberd., Mintlaw; Alexander Vass Anderson, M.B. Aberd., Stonehaven; Thomas Fraser,† M.A., M.B. Aberd., Aberdeen; Norman James Sinclair, M.B. Aberd., Aberdeen; and David Sivewright, M.A., M.B. Aberd., Strichen.

* Thesis considered worthy of commendation.
† With "credit."

KING'S COLLEGE, LONDON.—In the Faculty of Medicine the following scholarships and prizes have been awarded:—Sambrooke Exhibitions, Eardley Lancelot Holland, Thomas Henry Jones, and John James; Medical Entrance Scholarship, A. J. Wigmore; Warneford Scholarships, John Alexander Drake and Matthew Robert Cecil MacWatters; Senior Scholarship, Arthur Edmunds; Second Year Scholarship, Harold Benjamin Day; Junior Scholarships, Thomas Henry Jones and Eardley Lancelot Holland; Rabbeth Scholarship, Frederick Champ McCombie; Leathes Prize, Harold Balme and Colin James Galbraith; Warneford First Prize, Harold Balme; Warneford Second Prize, Edward Augustine Bell; Barry (Divinity), Arthur Donald Griffith; Tanner Prize, Edgar Winn Fox Dolman; Todd Prize, Arthur Edmunds; Hygiene Prize, James Duncan Clay; Pathological Anatomy Prize, Alfred Hocart Brehaut; Obstetric Medicine Prize, Archibald Douglas Reid; Forensic Medicine Prize, Archibald Douglas Reid; Medicine Prize, Archibald Douglas Reid; Surgery Prize, Frederick Charles Carle; Professor Rose's Surgery Prize, Hubert Liston Willcox; Anatomy Prize, Albert Angelo Myers; Physiology Prize, Albert Angelo Myers; Chemistry Prize, Albert Angelo Myers; and Materia Medica Prize, Albert Angelo Myers.

ST. GEORGE'S HOSPITAL.—Mr. H. H. Macpherson presided at a quarterly general court of the governors of St. George's Hospital in the board-room on July 13th, when Mr. T. Holmes, the treasurer, moved that the weekly board should be empowered to sell stock to the amount of £4000. He said that unless some large donations or legacies were received this step would be necessary in order to finish the work which was now under contract. If the motion were carried the weekly board would only exercise the power in case of necessity. There was a deficiency on the last year's expenditure, normal and extraordinary, of £15,000, the subscription list and the legacies both having been small.—Sir Henry Burdett, in seconding the motion, said that as a visitor he knew the need for the expenditure of £100,000 which had been incurred on reconstruction works. The present was an age of criticism and a political crisis had almost arisen out of hospital affairs in South Africa. He was not in this country when the criticism appeared or he would have felt himself called upon to point out that without special knowledge of the exact circumstances in South Africa that criticism was too narrow to warrant the amount of public attention which it had received. It was the first essential of criticism of hospital affairs that those who undertook it should have an accurate practical knowledge of the circumstances and matters of which they treated. It had been made a matter of complaint against St. George's Hospital that the expenditure was too great, and it had been suggested that if the present policy were continued and extended to other hospitals the time would soon arrive when the voluntary hospitals must be taken over by the State. That was exactly the opposite of the truth. What St. George's Hospital still suffered from was a margin of deficiency between income and expenditure which existed 10 years ago and which had never been wiped out. A great hospital like St. George's must advance with the age. Its sanitary conditions were now perfect, its means of isolating infectious cases were second to those of no other hospital in London, and the accommodation for the staff was a credit to the metropolis. He pleaded for a special effort on behalf of the institution. The hospital had never had a festival dinner, and he thought that if they were to ask for the assistance of a member of the Royal family who would place himself at their head in bringing to the knowledge of London generally, and especially of the inhabitants of that district, the need which existed for an extra £10,000 a year, they would not only get it, but they would get the £100,000, which they had so wisely expended upon buildings, restored to their reserve fund.

HOSPITAL ENDOWED BED.—The late Mr. Augustus Matthew Goddard bequeathed to St. Thomas's Hospital a legacy of £1000 to endow a bed, to be named the "Matthew and Patience Goddard Bed."

VACCINATION GRANT.—Mr. C. J. Perrott, public vaccinator for the Kingswood division of the Keynsham Union, has been awarded a grant for successful vaccination.

THE CRISIS IN CHINA.—Mr. George F. Stooke, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., stationed at I-chang, in the service of the Foreign Mission of the Church of Scotland, was reported safe on July 19th.

DR. AND MRS. J. PRIOR PURVIS, who were married at St. Pancras Church, Euston-road, on June 24th, 1840, celebrated the sixtieth anniversary of their wedding on June 24th last. A reception was held at Lansdowne-place, Blackheath-hill, when some 150 of the leading residents of the district were present to offer their congratulations. The family circle numbered 35, consisting of children, grandchildren, and a great-grandchild.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, MARYLEBONE-ROAD, N.W.—A meeting of governors and friends of Queen Charlotte's Hospital was held on July 20th at 22, Portman-square, when Viscount Portman (the President) presided. The Duke of Cambridge attended and the following amongst others were also present: Colonel FitzGeorge, Lord Hugh Cecil, the Earl of Hardwicke, Canon Duckworth, Lady Farquhar, Sir Edward Hertslet, Mr. and Mrs. F. W. Hunt, Mrs. Charles Inge, Mrs. Beauchamp, Colonel Gordon Watson, Mr. G. N. Taylor, General Lowry, Mrs. Hodgkinson, Mrs. Warde, Mr. and Mrs. H. A. Harben, Mr. H. J. Royds, Major McMahon, Miss Denison, Mrs. Ernest Waggett, Mr. and Mrs. Robert English, Mr. and Mrs. F. Herbert Davies, Mr. J. Dix Lewis, Mr. F. G. Cavendish Bentinck, Mrs. Fenwick B. Barron, Mrs. Anstey, Canon Barker, Rev. G. F. Forbes, Mrs. W. M. Beaufort, Mrs. Benjamin Taylor, Miss Alice Cox, Mrs. Newby, and the Rev. V. G. Borradaile. A report was presented showing that the enlargement of the hospital, which was commenced in 1897, had been completed, but that there were still some improvements required to the building, which it was estimated would cost about £2000. The Earl of Hardwicke (chairman of the Committee of Management) stated that in addition to the £2000 which were needed to accomplish the renovation of the hospital the increased expenditure for maintenance caused by the enlargement of the hospital and enhanced prices would amount to about £1000 per annum.—The Duke of Cambridge brought forward the following motion—

That this meeting desires to express its warm approval of the success which has attended the efforts made by the committee to provide increased and improved accommodation for the growing number of patients seeking the aid of the charity and cordially endorses the appeal for additional support to enable the committee to carry out the further work necessary for the complete renovation of the hospital—

and referred to the long connexion of his family with the institution. He expressed his pleasure at hearing that the hospital had opened its doors to the wives of soldiers and

sailors and reservists now at the front, 68 of whom had been granted admission as in-patients and 24 had been treated as out-patients.—Lord Hugh Cecil, M.P., seconded the motion. He dwelt on the great work which was done in the training school of the hospital in training medical students, midwives, and monthly nurses, which benefited all classes of the community.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

General Laurie and the Medical Act of 1858.

IN accordance with his notice General LAURIE introduced into the House of Commons on Friday, July 20th, his Bill for the extension of the provisions of the Medical Act of 1858 so as to entitle to registration the holders of certain colonial diplomas. The measure is backed by General Laurie himself, Mr. Rothschild, Sir Mancherjee Bhownaggree, Colonel Wyndham Murray, Mr. Middlemore, and Sir James Fergusson. Without going into the merits of the question it is safe to say that in the present state of Parliamentary business there is not the slightest chance of the Bill being passed.

Proposed Labour Licences for School Children.

The question of children of school age engaging in labour calculated to interfere with their education was discussed last week before the Grand Committee of the House of Commons on Law in connexion with the Elementary Education Bill. Mr. GEOFFREY DRAGE proposed to insert in the Bill a new clause for the establishment of a system of licensing under which the local authority would, on being satisfied on certain points, issue a licence to a child to labour and it would become an offence for an employer to engage an unlicensed child and for a parent or guardian to allow the child to be engaged. Sir JOHN GORST, the Minister in charge of the Bill, did not accept the proposed clause, but he announced that the Education Department are prepared to join with the Home Office in the appointment of a departmental committee to inquire into the whole question and frame legislation for introduction during the next session of Parliament.

HOUSE OF COMMONS.

THURSDAY, JULY 19TH.

Invalided from South Africa.

Mr. MACNEILL asked the Under-Secretary for War how many officers, non-commissioned officers, and men had been invalided from South Africa since the outbreak of the war; of these, how many had died on the passage home or in military hospitals or in their own homes, and how many had been incapacitated from further service by wounds or disease.—Mr. WYNDHAM replied: 20,658 have been invalided home; of these 63 died on the passage and 60 in military hospitals; there is no record of any having died in their own homes; 430 have been incapacitated from further service by wounds and disease.

Cholera in India.

Mr. SCOTT asked the Secretary of State for India whether, in view of the outbreak of cholera in the famine districts of India, any, and if so what, addition had been made to the famine medical service, and whether he could state the number of deaths from cholera in the famine districts.—Lord GEORGE HAMILTON replied: I am not able to state the number of additional medical officers and medical subordinates sent to the famine districts in consequence of the outbreak of cholera. I was informed that as regards the worst cholera tract in the middle of June the local authorities there had received as much extra medical help as they thought necessary. The returns which have reached me show that during the month of June the telegrams state that 22,198 cholera deaths were reported from British famine districts and there were 19,122 from native States similarly afflicted. During the three weeks ended on July 7th the reported cholera deaths averaged 6562 a week for British famine districts and 6185 a week for native States affected by famine.

FRIDAY, JULY 20TH.

The Medical Service in India.

Mr. SCOTT asked the Secretary of State for India whether the services of more than one medical man had been available at most of the large famine camps, containing from 20,000 to 30,000 people, at any time during the famine or since the outbreak of cholera.—Lord GEORGE HAMILTON replied: I have not received details as to the individual distribution of medical officers and medical subordinates at the different relief camps and relief houses. The famine codes contain full instructions for strengthening the medical staff in famine districts, for provision of hospital accommodation on relief works, for posting a medical officer or a subordinate qualified for independent charge to each hospital, and for the duties of such medical officers. The instructions as to engaging additional medical officers and subordinates from outside the regular service when need arises are full and clear.

Civil Surgeons in South Africa.

Dr. FARQUHARSON asked the Under-Secretary for War whether it was a fact, as stated by Mr. Burdett-Coutts in a letter to the newspapers, that civil surgeons employed in military hospitals in South Africa had been required by the Army Medical Department to sign a contract not to divulge in any way what their impressions might be on hospital matters?—Mr. WYNDHAM replied: Civil surgeons have to sign a contract, not being entitled to emoluments under the pay warrant or amenable to discipline under the Army Act. They have to sign a contract accepting the terms offered to them and the obligations of discipline, subject to the forfeiture of these terms. I have in my hand a copy of the contract. The only paragraphs that bear upon discipline are as follows: "During the said period I will devote my whole time and professional skill to my service hereunder, and will obey all orders given to me by commissioned military or naval officers or by the permanent medical officers of either of those services." And the next paragraph runs: "In case I shall complete my service hereunder to your satisfaction in all respects, I shall receive at the end of the said period a gratuity of two months' full pay at the rate hereinbefore specified, but in case I shall in any manner misconduct myself, or shall be (otherwise than through illness or unavoidable accident) unfit in any respect for service hereunder, of which misconduct or unfitness you shall be sole judge, you shall be at liberty from and immediately after such misconduct or unfitness to discharge me from further service hereunder, and thereupon all pay and allowances hereunder shall cease, and I shall not be entitled to any free passage home or gratuity." That is the only contract civil surgeons have to sign, and for my part I cannot see that it offers any support for the statement in question.—Mr. BURDETT-COUTTS said he desired to ask a question which, he thought, would contain a correction of detail and which added very largely to the force and significance of the statement referred to. He should like to ask whether it was not the case that when some letters had been published from doctors in South African hospitals they had to sign a statement to the effect that they were not to communicate their impressions of hospital matters to the public or that they were to take the consequences.—Mr. WYNDHAM: I have no knowledge of any such fact. That is the only contract we have made with civil surgeons and I am not aware of any other.—Sir HENRY CAMPBELL-BANNERMAN: Would it not be desirable to have some inquiry as to whether this declaration was ever enforced in South Africa? Telegraphic communication could soon be made.—Mr. WYNDHAM: There is no objection whatever.

MONDAY, JULY 23RD.

Anti-Typhoid Inoculation in South Africa.

Colonel WYNDHAM MURRAY asked the First Lord of the Treasury whether the instructions to the Commission of Inquiry into the Medical Arrangements in South Africa would include the making of a thorough inquiry on the spot by the medical members of the commission into the results of inoculation for typhoid fever in preventing the disease or lessening its effects.—Mr. BALFOUR replied: The inquiry to which my hon. and gallant friend refers, though doubtless one of very great importance, appears to me to be outside the scope of the reference to the commission, and probably it would require a commission of somewhat different constitution to investigate a purely scientific medical subject of the kind suggested.

Hospital Accommodation for China.

Mr. HEDDERWICK asked the Government what had been done to provide for the proper care of the British wounded at Tientsin and Taku; and whether there was any hospital accommodation at Wei-Hai-Wei.—Lord G. HAMILTON replied: Her Majesty's Government have no special information as to the arrangements made at the front for the wounded in the recent engagements, but there were available the medical staffs of the various British men-of-war under Admiral Seymour, and General Dorward took with him other medical officers and appliances. As regards hospital accommodation at Wei-Hai-Wei there is a good hospital on the island and good stone barracks convertible to hospital use if wanted. General Gaselee has telegraphed that as soon as he reaches Wei-Hai-Wei he will report on its suitability for the location of base hospitals. The water-supply on the island is good and ample. To this I have to add that the Government of India have already provided a hospital ship and are prepared to supplement this accommodation by converting three transports into hospital ships. The American hospital ship *Maine* has also been placed at the disposal of her Majesty's Government, and I am glad to take this opportunity of expressing our gratitude for this great act of generosity to the Atlantic Transport Company which has furnished the ship and to the American ladies who have provided the funds for equipping and maintaining it. I have also to inform the House that I have received from the Maharajah Sindhia of Gwalior the offer of a fully-equipped hospital ship for China, upon which he is willing to spend 20 lakhs. This princely offer is made on behalf of himself, his mother, and his wife, to testify their loyalty to her Majesty the Queen-Empress. Her Majesty's Government have expressed their acceptance of this most munificent offer and their deep appreciation of the motives which actuated his Highness to make it.

TUESDAY, JULY 24TH.

Results of Anti-Typhoid Inoculation.

Mr. CHANNING asked the Under Secretary of State for War whether he was aware that the Director-General of the Army Medical Department, at the Indian Medical Service dinner on June 14th, stated that the results of inoculation for typhoid fever, while it afforded some protection against contracting the disease, rather increased the risk of death when contracted, but that this only applied to the men, as both the incidence and case mortality among officers appeared to be increased by inoculation; and whether the recent statistics of Professor Wright of Netley, which show that both attacks and deaths from typhoid fever were seven times less in the inoculated than in the uninoculated, applied equally to officers and men separately.—Mr. WYNDHAM replied: I have no knowledge of the statement attributed to the Director-General of the Army Medical Department, and, as I have already explained to the House on more than one occasion, the statistics at present available are not sufficient to enable me to give a satisfactory reply to the question.

Medical and Nursing Staff in the Orange River Colony.

Dr. TANNER asked the Under Secretary of State for War if he had any official information showing that, in consequence of the arrangements, out of 24 nurses employed in the Orange River Colony 14 had succumbed; and, whether 100 more doctors and 200 nurses were now required and stores stacked at base were to be sent up to the front.—Mr. WYNDHAM replied: Eight nurses have died in South Africa. Lord

Roberts has quite recently asked for 20 more surgeons and 50 nurses. These are being sent. It is usual for stores to be stacked at the base and sent up as required.

A Cow with a Tuberculous Udder.

Mr. FIELD asked the President of the Local Government Board (1) whether he was aware that at a recent meeting of the Northwich Rural Council a communication was received from the county medical officer of health, Dr. Vacher, stating that he was informed by the medical officer of health for Manchester that a cow with a tuberculous udder had been found on a farm in West Cheshire; that Dr. Niven wrote to Dr. Vacher advising to isolate the infected cow, to dry her at once, and have her fed for slaughter; (2) whether the Local Government Board had sanctioned such a system; and (3) whether he was aware that Dr. Vacher, in conjunction with the late Inspector Wagstaffe, inaugurated and carried out a series of tuberculous prosecutions in Birkenhead.—Mr. CHAPLIN: The facts appear to be substantially as stated in the first paragraph. The cow, however, was not sold but was destroyed by the farmer. The answer to the second paragraph is in the negative. Dr. Vacher, before becoming county medical officer was medical officer of health for Birkenhead, and I am informed that during this period the Birkenhead Town Council, as advised by him, arranged for a much more thorough inspection of meat intended for the food of man than had previously been attempted and appointed Mr. Wagstaffe to give his whole time to the work. Dr. Vacher, however, appears to have had nothing to do with the present case except to inform the Northwich Rural District Council of the communication which he had received from Dr. Niven.

Medical Practice and Company Law.

At this sitting the House took the report stage of the Companies Bill, and at the commencement of the proceedings it was decided to strike out of the Bill Clause 2 applying the Pharmacy Act to companies carrying on business as chemists and druggists and Clause 3 declaring that it shall not be lawful for a company to carry on the profession or business of a physician, surgeon, dentist, or midwife.—Colonel WELBY moved to strike out the former clause.—Mr. RITCHIE, President of the Board of Trade, the Minister in charge of the Bill, said he felt himself unable to resist the motion. In the Standing Committee he himself had recommended that this clause and Clause 3 should be omitted, but his recommendation was not adopted by the Committee. He did not propose to enter into the merits of either clause, though he admitted that there were evils which required to be dealt with. He did not desire to commit himself as to the particular mode by which the evils should be remedied. His main object in assenting to the motion was that in his opinion the clauses were not germane to the Bill. He knew of no instance in which in all the various Companies Acts there had been any attempt whatever made to say who should and who should not carry on companies. They had all been Acts dealing with machinery and the creation and formation and administration of companies.—Mr. BRYCE said that he took the same view of this matter as the President of the Board of Trade. He admitted that the two clauses dealt with important subjects. He thought these subjects ought to be dealt with, and he thought that they ought probably to be dealt with even more strongly than they were dealt with in the clauses now before the House. But they raised questions quite apart from the machinery with which this Bill was concerned, and he thought it better to leave the clauses out of the Bill.—Mr. GIBSON BOWLES thought the House ought to know how it came about that these clauses appeared in the Bill.—Mr. RITCHIE explained that they were inserted in the House of Lords, and he considered it only proper and courteous to the House of Lords that the Bill should be introduced in this House in the form in which it came from the House of Lords.—Sir WALTER FOSTER said that he hoped the House would not omit the clauses. They had received a great deal of consideration. They had been in the Bill in two successive sessions. They were introduced originally in a separate Bill and the Lord Chancellor himself deliberately put them into the Bill as the best method of regulating certain dangers and difficulties to which the public were exposed in the existing state of the law. The thing was done after consultation with the persons affected. Not in the interest of any class, but in the interest of the public generally, he appealed to the Government to retain the clauses and not to yield to the clamour of a particular class. He felt that if they were omitted an opportunity would be lost of protecting the public against many forms of illegal practice in pharmacy, medicine, and dentistry. He did not think that there should be a panic because of the opposition of certain trading interests affected by the clauses.—Sir JAMES HASLETT spoke in support of the omission of the clauses.—Mr. LAWSON WALTON said that there was no question of clamour or of opposition from a particular class. It was the duty of this House to pass legislation which could be easily referred to and which would be free from confusion, and he submitted that if these clauses were retained they would cause confusion and make the statute difficult to refer to. These clauses were, in his opinion, entirely out of place in this Bill, and he hoped that the House would strike them out.—Colonel LONG argued that the President of the Board of Trade had given no sufficient reason for saying that the clauses were not germane to the Bill. Surely the object of the measure was to put down abuses in connexion with companies. Certain abuses were known to exist in connexion with medical, dental, and pharmacy practice and the Lord Chancellor had thought fit, after considering the evidence, to insert these clauses.—Sir J. BATTY TUKE said that he regretted that Clause 3 was to be dropped, as its action would be to put a stop to practices which served to paralyse the action of the Medical Acts in certain important particulars. Under the law now existing persons in no way connected with the medical profession were able to form companies the object of which was to act as physicians, surgeons, and dentists. Over such companies the General Medical Council could exercise no jurisdiction, and one of the main objects of the Medical Acts was inoperative. The public were the sufferers, as it was rendered impossible to distinguish between qualified and unqualified practitioners. He recognised that the clause was not germane to the general tenor of the Bill, but he felt so strongly on the subject that he would take an early opportunity next session of introducing a Bill dealing with the subject.—The motion for the omission of Clause 2 was then put to the House and agreed to without a division.—Mr. MADDISON moved to omit Clause 3.—This motion was also agreed to without a division.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ANDREW, B. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Long Crendon Sanitary District of the Thame Union, vice M. H. Humphreys, resigned.

BULLMORE, W. K., M.D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health by the Falmouth Town Council.

BUSTEED, J. H., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Ellesmere and Welshampton Sanitary Districts and for the Workhouse of the Ellesmere Union, vice J. W. Roe, resigned.

CHADBORN, C. N., L.R.C.P. Lond, M.R.C.S., has been appointed House Surgeon to the Sussex County Hospital, Brighton.

COSTINE, W. C., M.R.C.S., has been appointed Public Vaccinator for the Kirkdale Division of the West Derby Union.

DAVIS, J. H, M.B, B.Ch. Irel., has been appointed Assistant Medical Officer at the Brownlow Hill Workhouse, Parish of Liverpool, vice E. Smith.

DAVIES, H. H., M.R.C.S., has been appointed Medical Officer of Health for the Uwchaled Sanitary District, vice R. T. Davies.

DENYSSEN, P. J., L.R.C.P. Lond, M.R.C.S., has been appointed Medical Officer of Health for the Halesworth Urban District.

EMMETT, RICHARD, L.R.C.P. Lond., M.R.C.S, has been appointed Certifying Surgeon under the Factory Acts for the County Borough of Portsmouth and the Civil Parish of Cosham in Fareham Rural District.

ENSOR, HENRY COLLEN, M.R.C.S., has been appointed Ophthalmic Surgeon to the Cardiff Provident Dispensary and to the Cardiff Infirmary.

FEY, W. L., M.B., B.Ch. Oxon., has been appointed Medical Officer for the Catterick and Scorton Sanitary Districts of the Richmond Union, Yorks, vice H. M. Eyres, resigned.

FORSTER, LUCINDA, M.B., B.S. Lond., has been appointed House Surgeon to the Bristol Royal Hospital for Sick Children and Women, St. Michael's Hill.

GOTT, J., L.S.A., has been appointed Medical Officer for the Ringwood Union and Certifying Surgeon under the Factory Acts for the Ringwood Rural District in the county of Southampton.

HALL, G. C., M.R.C.S., has been appointed Medical Officer for the Ottmoor Sanitary District of the Headington Union, vice C. Black, resigned.

HANLY, T. F., L.R.C.P, L.R.C.S. Edin., has been appointed Certifying Surgeon under the Factory Acts for the Gillingham District of Dorset.

HERBERT, A. W. C., L.S.A., has been appointed Certifying Surgeon under the Factory Acts for the Southwold District, Suffolk.

HIRSCH, CHARLES J. W., M.R.C.S., L.R.C.P. Lond, L.S.A., has been appointed Public Vaccinator for Woolwich.

LESLIE, L. F., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Kvesham Union, vice H. E. Haynes, resigned.

MARTIN, J. P., L.R.C.P. Irel., L.R.C.S., has been appointed Assistant Medical Officer at the Brownlow Hill Workhouse, Parish of Liverpool, vice W. B. Bennett.

MCCALL, EVA, M.B., C.M. Glasg., has been appointed Resident Medical Officer of the Union Infirmary, Salford.

NEECH, J. T., L R.C.P. Edin., L.F.P.S. Glasg., D.P.H. Vict., has been appointed Medical Officer of Health for the Borough of Halifax.

NOLAN, H. F., L.R C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Third Sanitary District of the West Ashford Union, vice J. H. Mitcheson, deceased.

NOWELL, WALTER SALMON, M.A. Oxon., L.R.C.P., M.R.C.S., L.D.S. Eng., has been appointed Assistant Dental Surgeon to the Middlesex Hospital.

PENDLEBURY, H. S., M.B., B.C. Camb., F.R.C.S. Eng., has been appointed Assistant Surgeon to St. George's Hospital, Hyde Park Corner, S.W.

PRICE, D., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer for the Saddleworth Union.

RIMELL, A. T., L.R.C.P. Edin., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the Long Sutton District of Lincolnshire.

ROUSE, E. R., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer for the Ticehurst Union, vice W. H. Hall, resigned.

SCATCHARD, J. P., M.B., B.S. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Tadcaster Sanitary District and the Workhouse of the Tadcaster Union, vice T. B. Ireland, resigned, and Certifying Surgeon under the Factory Acts for the Tadcaster District of the West Riding of Yorkshire.

SHEILD, A. M., M.B., B.C. Camb., F.R.C.S. Eng., has been appointed Surgeon to St. George's Hospital, Hyde Park Corner, S.W., vice T. Warrington Haward.

SMITH, E. J., L.R.C.P. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Walton-on-Naze District of Essex.

STOKES, C. E., M.D. Dubl., B.Ch., has been appointed Medical Officer for the Brampford Speke Sanitary District of the St. Thomas Union, Exeter, vice T. Smith, resigned.

SWAINSTON, ELIOT, M.B., B.S. Durh., has been appointed House Surgeon to the North-Eastern Hospital for Children, Hackney-road, Shoreditch, N.E.

SYMONS. W. H., M.D. Brux., L.R.C.P. Lond., M.R.C.S., D.P.H. Oxon., has been re-appointed Medical Officer of Health by the Bath City Council.

WHITE, P. S., L R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Bugbrooke Sanitary Division of the Northampton Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £150 per annum, with an allowance of £30 yearly for cab-hire, with furnished rooms, fire, lights, and attendance.

BIRMINGHAM WORKHOUSE.—Medical Officer for three weeks from the middle of August. Board, apartments, laundry, and attendance provided. Apply, stating terms, to the Clerk to the Guardians, Birmingham.

BOSCOMBE HOSPITAL, Bournemouth.—House Surgeon. Salary £60 per annum, with board, lodging, and washing. No beer or spirits.

BRECON INFIRMARY, No. 6, Bulwark, Brecon, South Wales.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, fire, and gas.

BRISTOL EYE HOSPITAL.—Locum Tenens for the House Surgeon for two months. Salary 2½ guineas a week, without residence.

BRISTOL ROYAL INFIRMARY.—Honorary Ophthalmic Surgeon.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c.

CITY OF SHEFFIELD.—Assistant Resident Medical Officer for the two City Hospitals. Salary £120 per annum, with board, lodging, and attendance. Apply to the Town Clerk, Town-hall, Sheffield.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising £10 annually to £150, with board, furnished apartments, &c.

CORPORATION OF BIRMINGHAM.—CITY HOSPITAL, Lodge-road.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, &c.

CUMBERLAND INFIRMARY, Carlisle.—House Surgeon for one year. Salary £70 per annum, with board, lodging, and washing. Also Assistant House Surgeon for seven months from Oct. 1st. Salary at the rate of £40 per annum, with board, lodging, and washing.

DENBIGHSHIRE INFIRMARY, Denbigh.—House Surgeon for 12 months. Salary £100, with board, residence, and washing.

DEVONSHIRE HOSPITAL, Buxton, Derbyshire.—Assistant House Surgeon. Salary £50 per annum, with furnished apartments, board, and washing.

DUMFRIES AND GALLOWAY ROYAL INFIRMARY, Dumfries.—House Surgeon. Salary £50 per annum, with board and washing.

DURHAM COUNTY ASYLUM, Winterton, Ferryhill.—Junior Assistant Medical Officer. Salary £140, rising £10 annually to £160, with board, laundry, and attendance.

EAST SUFFOLK AND IPSWICH HOSPITAL, Thorofare, Ipswich.—Second House Surgeon, unmarried. Salary £60, with board, lodging, and washing.

HAMPSTEAD HOSPITAL, Parliament-hill, N.W.—Resident Medical Officer for six months. Salary at the rate of £120 per annum, with rooms, coals, and gas.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY, 74, King-street, South Shields.—Junior House Surgeon. Salary £75 per annum, with residence, board, and washing.

LONDONDERRY COUNTY BOROUGH.—Medical Officer to act as Medical Superintendent Officer of Health and Medical Attendant at Foyle Hill Infectious Diseases Hospital. Salary £350 per annum. Apply to the Executive Sanitary Officer's Office, Guildhall, Londonderry.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence at the institution.

MANCHESTER EAR HOSPITAL.—Clinical Clerkship for a Senior Student for six months. Honorarium 10 guineas.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Assistant Medical Officer to the Out-patient Department, Hardman-street, Manchester. Honorarium £40 per annum.

NEWCASTLE-UPON-TYNE CITY ASYLUM, Gosforth, Newcastle-upon-Tyne.—Assistant Medical Officer, unmarried. Salary £130 a year, with furnished apartments, board, &c., rising £10 annually to £150.

NORTHAMPTON GENERAL INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with furnished apartments, board, attendance, and washing.

NORTH CAMBS. HOSPITAL, Wisbech.—Resident House Surgeon. Salary £130 per annum, with furnished house.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch.—Resident Medical Officer for 12 months. Salary £120 per annum, with board, residence, and washing. Apply to the Secretary, City Office, 27, Clement's-lane, Lombard-street, E.C.

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon, unmarried. Salary £140 per annum, all found except board.

OLDHAM INFIRMARY.—Junior House Surgeon for one year. Salary £75, with board, residence, and washing.

PARISH OF ROUSAY AND EGILSHAY, Orkney.—Resident Medical Officer. Salary £51 sterling per annum. Apply to Inspector of Poor, Rousay, Orkney.

ROYAL HALIFAX INFIRMARY.—Senior House Surgeon, unmarried. Salary £120 per annum, with residence, board, and washing. Also Second House Surgeon, unmarried. Salary £100 per annum, with residence, board, and washing. Also Third House Surgeon, unmarried. Salary £80 per annum, with residence, board, and washing.

ROYAL INFIRMARY, Sheffield.—Junior Assistant House Surgeon. Salary £70 per annum, with board, lodging, and washing.

RUBERY-HILL ASYLUM, Barnt Green, Worcestershire.—Junior Assistant Medical Officer, unmarried. Apply to Medical Superintendent.

ST. BARTHOLOMEW'S HOSPITAL, Rochester.—Assistant House Surgeon. Salary £100 per annum, with board, washing, firing, and lights.

SOUTHPORT INFIRMARY.—Resident Junior House and Visiting Surgeon for six months. Honorarium at the rate of £50 per annum, with board, residence, and washing.

STAMFORD-HILL AND STOKE NEWINGTON DISPENSARY, 189, High-street, Stoke Newington.—Assistant Resident Medical Officer. Salary £100 per annum, with board.

THE CHIEF INSPECTOR OF FACTORIES gives notice of a vacancy of Certifying Surgeon under the Factory Acts at Syston, in the county of Leicester.

TOTTENHAM HOSPITAL, N.—House Surgeon for six or 12 months. An honorarium at the rate of £20 per annum given, with board, residence, and laundry.

VICTORIA HOSPITAL FOR CONSUMPTION, Craigleith, Edinburgh.—Resident Physician. Residence and board and nominal honorarium in lieu of conveyance. Also non-resident Clinical Assistant. Honorarium at the rate of £60 per annum. Both appointments for six months. Apply to the Hon. Secs., 1, North Charlotte-street, Edinburgh.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £75, with board, residence, &c.

WILTS COUNTY ASYLUM, Devizes.—Assistant Medical Officer, unmarried. Salary £130, rising £10 a year to £160, with board, residence, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—Assistant House Physician for six months. Honorarium at the rate of £75 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BRADLEY.—On July 18th, at Greville House, Raynes-park, Wimbledon, S.W., the wife of James Edmund Campbell Bradley, M.B., B.C. Cantab., of a daughter.

CUNNINGHAM.—On June 25th, at The Mount, Glossop-road, Sheffield, the wife of R. Wiseman Cunningham, M.B., C.M., of a son.

PATON.—On July 17th, at Lynedoch-place, Edinburgh, the wife of D. Noel Paton, M.D., of a son.

PRATT.—On July 19th, at Heaton-road, Newcastle-on-Tyne, the wife of E. F. Pratt, M.B., of a son.

MARRIAGE.

PAYNE—DERRY.—On July 19th, at the Wesleyan Church, Streatham, Joseph Lewin Payne, L.R.C.P., M.R.C.S., L.D.S. Eng., of Devonshire-street, Portland-place, to May Castine Derry, youngest daughter of Charles J. D. Derry, of The Woodlands, Tooting-common.

DEATHS.

BENNETT.—On July 19th, at Maidenhead, Berks, William Charles Storer Bennett, F.R.C.S., of George-street, Hanover-square, W., aged 48 years.

CAMERON.—On July 18th, at Chipping Campden, Gloucestershire, Archibald Henry Foley Cameron, M.R.C.S., L.R.C.P. aged 71 years.

CROKER.—On July 18th, at Claremont, Seaford, Sussex, Surgeon-Major Arthur Croker, late Army Medical Department, in his 69th year.

PRESCOTT.—At Great Queen-street, W.C., Thomas Prescott, M.R.C.S., L.R.C.P., aged 52 years.

SHEWEN.—On July 18th, at Lindenhurst, Sevenoaks, Kent, Alfred Shewen, M.D. Lond., of Sydney, N.S. Wales, Senior Consulting Hon. Physician to Prince Alfred's Hospital of that city, in his 57th year.

WRIGHT.—On July 20th, at Vanbrugh-park, Blackheath, Brigade-Surgeon Thomas Wright, late Army Medical Department, aged 68 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PAY OF DISTRICT SURGEONS IN CAPE COLONY.

WE extract the following from the *Cape Gazette*:—

GOVERNMENT NOTICE.—No. 319, 1900.

Colonial Secretary's Office,
Cape Town, 8th May, 1900.

VACANT DISTRICT SURGEONCIES.

INTENDING Candidates are invited to make early application for the following District Surgeoncies, now vacant, viz.:—

1. Hay (Additional), resident at Postmasburg. Allowance £40 per annum, and private practice.

2. Fraserburg (Additional), resident at Williston, vacant by the resignation of Dr. ——. Allowance £50 per annum, and private practice.

3. Namaqualand (Additional), resident at Garies. Allowance £100 per annum, and private practice.

4. Tabankulu, vacant by transfer of Dr. ——. Allowance £200 per annum, inclusive of forage allowance, £50 per annum, and private practice.

5. Flagstaff, vacant by resignation of Dr. ——. Allowance £200 per annum, including forage allowance of £50, and private practice.

6. Mount Fletcher, vacant by resignation of Dr. ——. Allowance £200 per annum, inclusive of forage allowance of £50 per annum, and private practice.

NOEL JANISCH,
Under Colonial Secretary.

Medical men will be interested to see the value that is set upon them. The remuneration offered by the Government of Cape Colony is hardly likely, we think, to tempt many of our readers to a colonial life.

THE INTERRUPTED ELECTRICAL CURRENT IN CHRONIC COMPLETE DEAFNESS.

To the Editors of THE LANCET.

SIRS,—I am treating a case of chronic and extreme deafness (the cause of which is unknown to me) by the application of the interrupted electrical current. After about a week's treatment the hearing has, I believe, slightly improved and the patient tells me that he has to-day heard the brewery steam gong for the first time for years. Could you tell me if this treatment has been found beneficial in other cases of deafness? I am, Sirs, yours faithfully,

DIGBY F. B. COTES, M.R.C.S. Eng.

Burton-on-Trent, July 21st, 1900.

*** It is obvious that in many cases of chronic complete deafness no electrical current could restore or improve hearing. In others some good might follow the treatment. Our correspondent does not tell us how, when, or where the electricity is applied. The cause of the condition is the important point.—ED. L.

A POINT UNDER THE CORONERS ACT.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you would refer me to any authority as to the law on the following case. A man was brought dead to my hospital the other day and there were no signs as to how he met his death. The coroner ordered me to make a post-mortem examination, which I did, and attended the inquest afterwards and gave evidence. I claimed the usual fee, £2 2*s*., for the work, when the coroner asked me to show him the authority on which I based my claim. House surgeons are not entitled to fees for such work when the patient has died *in* the hospital, but if brought dead to the hospital and an inquest is held, or if a post-mortem examination and an inquest are held and the house surgeon is summoned to attend, I believe the house surgeon receives the usual remuneration. Such has been my previous experience.—I am, Sirs, yours faithfully,

July 16th, 1900. R.M.O.

*** The authority governing this question is contained in the 22nd section of the Coroners Act of 1887 (50 & 51 Vict., c. 71) which runs as follows:—"§ 22. A legally qualified medical practitioner who has attended at a coroner's inquest in obedience to a summons of the coroner under this Act shall be entitled to receive such remuneration as follows—that is to say: (*a*) for attending to give evidence at any inquest whereat no post-mortem has been made by such practitioner, one guinea; and (*b*) for making a post-mortem examination of the body of the deceased, with or without an analysis of the contents of the stomach or intestines, and for attending to give evidence thereon, two guineas. Provided that (1) any fee or remuneration shall not be paid to a medical practitioner for a post-mortem examination instituted without the previous direction of the coroner; (2) where any inquest is held on the body of a person who has died in a county or other lunatic asylum, or in a public hospital, infirmary, or other medical institution or in a building or place belonging thereto or used for the reception

of the patients thereof, whether the same be supported by endowments or by voluntary subscriptions, the medical officer whose duty it may have been to attend the deceased person as medical officer of such institution as aforesaid, shall not be entitled to such fee or remuneration." It seems perfectly clear from the above that the coroner was wrong in refusing the fee asked for, unless he believed that the deceased died in the hospital. Perhaps if the section were laid before him he wou'd consider it now. Otherwise the precise remedy of the medical man is not very clear, but it seems to be by suing the coroner in the county-court. This is not a satisfactory proceeding where the amount is small owing to the small amount of costs recoverable, but the plaintiff by clearly stating the facts and citing the section given and the twenty-sixth section, which orders the coroner to pay costs, might be able to make good his case without legal assistance.—ED. L.

"UPWARD *versus* DOWNWARD VENTILATION."

THIS is the title of a little pamphlet which has reached us from Messrs. Robert Boyle and Son of 64, Holborn Viaduct. It contains extracts from the report of Professor Woodbridge on the ventilation of the Capitol, Washington, U.S.A. What Messrs. Robert Boyle and Son maintain is that when natural ventilation is properly and scientifically applied it invariably proves more successful than mechanical or other forms of artificial ventilation and it has the advantages that it cannot get out of order or break down, and costs but little to apply and maintain. In addition, the book contains excerpts from well-known authorities who condemn the downward ventilation of the Plenum system.

"THE DUTIES OF A PUBLIC VACCINATOR."

To the Editors of THE LANCET.

SIRS,—I am much obliged to you for your answer to my letter in THE LANCET of July 14th (p. 148), *re* vaccination prosecutions. Thinking the result of prosecution in this district may be of interest, I send a few lines to let you know. Three cases came before the magistrates, and in each case a fine of 1*s.* and costs was inflicted, the costs to include a fee of 10*s.* 6*d.* per case to the medical men subpœnaed to give evidence. I am not certain, but I think in cases prosecuted in the future that the vaccination officer's evidence will be sufficient to convict, without the public vaccinator appearing in court.

I am, Sirs, yours faithfully,

July 17th, 1900. X.

A PATENT AUTOMATIC BEVERAGE MACHINE.

WE learn that it is proposed to introduce shortly for out-door public use an automatic machine for the supply of non-alcoholic beverages—soda-water, lemonade, ginger-beer, &c. The principle of the penny-in-the-slot will be employed. The act of dropping the coin releases to each customer a collapsible cup which when placed in position under a delivery tube receives on turning a handle a cupful of beverage either effervescent or still. We are glad to notice that every precaution is promised in regard to the cleanliness and purity of the drinks supplied and of the drinking vessels. We fear, however, that certain difficulties will be encountered in thus attempting to place an automatic supply of beverages before the public. Imagine, for example, the machine being bombarded by the sun's rays in weather of the kind that we are now experiencing. The drinks would be somewhere between hot and cold unless the machines were jacketed with an ice chamber. Then special care will have to be taken to avoid metallic impurity. The idea is good in some respects. Some guarantee could be afforded of the purity of the beverages and the recourse to a stuffy or otherwise unpleasant bar or counter could be avoided. The particulars of the invention may be had from the Patent Automatic Beverage Machine Company, of 60, Chancery-lane, W.C.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—Mr. Harris's letter under the above heading in THE LANCET of July 14th, page 147, makes extremely pretty reading, but as an answer to a question, asking for some figures whereby one can base opinion as to the efficiency claimed by its supporters of the Krohne inhaler, it is an ingenious way of "begging the question." It is all very well to quote "If they hear not Moses and the Prophets," but is everybody as satisfied as Mr. Harris that the Krohne inhaler is the present-day representative of the ancient Hebrew law-giver and that its supporters are "the Prophets"? The Krohne Inhaler 1900 can only, in the natural order of events, be on its trial, as six months use of a new instrument by a comparatively small number of observers cannot be considered conclusive. I cannot anywhere in any of the journals or medical papers find any statistics whatever relating to the Krohne inhaler, so that one is absolutely in the dark as to how often it has been used; but I do find recorded in THE LANCET of Nov. 4th, 1899, page 1227, a death with the Krohne and Sesemann inhaler, so it would appear both from that and also from Mr. Harris's carefully guarded statement "that (the Krohne inhaler of 1900) in the hands of any ordinary practitioner with common sense could *hardly ever result* in death," that it is possible to have a fatality even when one has given attentive hearing to "Moses and the Prophets." In THE LANCET of August 19th, 1899, page 515, is an account of a death from chloroform anæsthesia with the statement that at the Children s Hospital, Birmingham, since the opening up to that date, 14,500 cases of anæsthesia had occurred and that only one death had taken place in that number; again, at the Royal Southern Hospital, Liverpool, where chloroform by the "rule-of-thumb" method is almost exclusively used, there has never been a death recorded since the opening—I cannot at the moment tell how many years that is, but I know it is considerably over 20, and the average number of operations being about 30 per week, that will give another big list of figures to the credit side of the "rule-of-thumb" method. Even the greatest advocate of the Krohne inhaler, Dr. Edmunds, does not pretend to claim its absolute infallibility, as anyone may read in his letter in THE LANCET of Oct 28th, 1899, p. 1205. He there plainly states that it is not only the inhaler but the man using it which has everything to do with the result attained. Another fact I wish to insist upon is, what does it matter about registering the exact amount of chloroform used to a drop? Everyone must realise that no two patients require the same amount of the drug to ensure an equal degree of anæsthesia and that the rule of averages is an absolutely fatal one to go by; what would kill outright one patient will not get another one under at all. Another objection to the Krohne inhaler is the time taken to get a patient under, and time is of importance where from 10 to 14 operations are to be performed in an afternoon; but, still, one would set aside that if it were conclusively proved that the new method was an absolutely safe one, which I maintain has not been done yet. Give us some facts and figures to go on; do not quote single cases where a man has taken chloroform in a Krohne inhaler and went off without "any coughing, struggling, or any unpleasant effects whatever"—that is no use at all. One has seen dozens of patients put under by the "rule-of-thumb" method with exactly the same state of affairs. Passing over the rather childish parallel of the weighing or guessing out of strychnine, I shall welcome any reply from Mr. Harris which contains a list of a sufficiently large number of cases of anæsthesia with the Krohne inhaler, also at the same time a record of the casualties.

I am, Sirs, yours faithfully,

Liverpool, July 16th, 1900. FRANK E. MARSHALL, M.B. Vict.

A SURGEON'S FEES.

THE hearing of the case of Collier *v.* Epstein was concluded on July 18th in the Queen's Bench Division before Mr. Justice Kennedy and a special jury. The action was brought by Mr. M. P. M. Collier, of Harley-street, against the widow of Mr. Ludwig Epstein, of Twickenham, to recover £152 5s., balance of fees amounting to 180 guineas alleged to be due in respect of certain surgical operations and subsequent attendance upon the defendant's husband. The jury came to the conclusion that 120 guineas, less the 35 guineas already paid, would be a fair and reasonable remuneration for the operation and attendance, and gave a verdict accordingly. Judgment was therefore entered for the plaintiff for £89 5s.

"WORD-BLINDNESS."

To the Editors of THE LANCET.

SIRS,—I am much obliged for Dr. J. Edmunds's instructive letter and references (THE LANCET, June 16th, p. 1767) chiefly as to paralytic aphasia, but I should like to repeat my question as to those typically pure and uncomplicated cases mentioned (pages 1506–8), where not one of "the various channels of receptivity was affected" save the recognition of the small naked outlines of print. Where there was no difficulty in naming objects from the small pictures of them in a spelling-book, if the letters were first introduced as distinctively coloured objects which could be grasped, involving the cheiro-kinæsthetic and muscular memories (from the weight) and the tactile memory (from variety of textures and materials), would not the ordinary printed letters be recognised as pictures of these?

I am, Sirs, yours faithfully,

Upper Bedford-place, W.C., July 11th, 1900. C. G. S. MENTEATH.

PS.—If the letters were not recognised as the same as the coloured models then it would be helpful to the patient to draw and colour the letters (J. Wyllie, 1894, p. 350). If there is anything in coloured audition or pseudo-chromæsthesia (*s. v.* Tuke, Dictionary of Psychological Medicine), and normal persons have practically used it (Popular Science Monthly, July, 1891, p. 372), also the blind who have once seen (Memorabilien, Heilbronn, 1882, ii., 524–36), and the deficiency of one memory is frequently compensated by the increased memory of of another sense, especially of hearing, the colours and shades of colours should give great assistance. The letters might be named after their colours: blue = *b*; pale blue = *p*; and crimson, cerise = *c*. Only 26 characters need be considered, as most of the capitals are the same as or resemble, the corresponding small letters (it would be almost possible to read without the knowledge by heart of the remainder). Moreover, as the vowels in one case were remembered while the others were forgotten they might be left plain; semi-vowels and the aspirate might be white. But it is in syllable- or word-blindness that the colours would be most useful, as, since juxtaposed colours sometimes mostify, run into each other, "kill," or, on the other hand, set each other off, the patterns or colour complexes of the syllables might obtain some manner of registration in the brain. Thus harmonies or colours would be easily recognised, and combined consonants would be remembered as one colour where they mingled together. The vowels not being coloured the distinctive outlines of the syllables would come out, although it is said that when words are coloured they usually acquire their colour from the vowels which seem to be

the most frequently coloured (Memorabilien). If, however, it were still difficult to remember what colours to chalk the printed letters, then the three primary colours and their shade-varieties respectively would have to be assigned to three principal shapes of letters—the small ones as *n, m, r, c, s, z*; those above the line *b, d, t, f, k, l*; and those below *p, q, g, j*—and still be named after their colours.

A CORRESPONDENT writes:—"Can any reader of THE LANCET recommend a good place to which to send a young woman for instruction in gymnastics of the chest? She wants to learn to expand her chest and has weak erectores spinæ. Somewhere in central or western London would be convenient."

SATURDAY (4th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

BRITISH MEDICAL ASSOCIATION MEETING AT IPSWICH.

DURING the forthcoming meeting of the British Medical Association at Ipswich the representatives of THE LANCET can be consulted at the Great White Horse Hotel, Ipswich, with regard to our reports of papers and proceedings.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

During the week marked copies of the following newspapers have been received: *Liverpool Daily Post, Morning Herald, Lisburn Standard, Sussex Daily News, Gazette (Middlesbrough), Bristol Mercury, Hereford Times, Norwood Review, Derbyshire Courier, Ilkley Free Press, Midland Free Press, Montrose Standard, Cleckheaton Guardian, Bexhill Chronicle, Gloucester Journal, Oxford Chronicle, Times of India, Pioneer Mail, Surrey Mercury, Lancashire Post, Grimsby News, Dundee Advertiser, New York Sun, Manchester Guardian, Western Mail, Sheffield Daily Telegraph, Scotsman, Citizen, Builder, Architect, Yorkshire Post, City Press, Leeds Mercury, Shanghai Mercury, Cape Register, Vegetarian, Newark Advertiser, Westminster Budget, Sydney Mail, Reading Mercury, Hertfordshire Mercury, Local Government Chronicle, Loughborough Examiner, St. Helens Newspaper, Buckingham Express, Bicester Herald, Bolton Evening News, Hastings News, Science Siftings, South-Eastern Gazette, Oswestry Advertiser, Church Bells, Surrey Advertiser, Bolton Journal, Daily Record, Glasgow Weekly Free Press and Aberdeen Herald, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Mons. F. Alcan, Paris; Messrs. Armbrecht, Nelson, and Co., Lond.; Anderson's Medical School, Glasgow, Secretary of; Messrs. Armour and Co., Lond.; Messrs. Arnold and Sons, Lond.; Messrs. Allen and Hanburys, Lond.

B.—Mr. F. E. Bissell, Anstey; Mr. A. S. Barrow, Indwe, Cape Colony; Messrs. Battle and Co., Neuilly-sur-Seine; British Fuel Economiser, Lond.; Messrs. Burgoyne, Burbidges, and Co., Lond.; Mr. C. Bullmore, Falmouth; Mr. A. Boswell, Brentwood; *Birmingham Daily Post*; T. B. Browne, Ltd., Lond.; Messrs. Burroughs Wellcome and Co., Lond.; Bristol Royal Infirmary, Secretary of; British Institute of Undertakers, Lond.; Secretary of; Mr. E. M. Bowden, Lond.; Mr. W. H. Brooks, Leicester; Messrs. C. Barker and Sons, Lond.

C.—Dr. N. H. Choksy, Bombay; Messrs. Crossley and Co., Lond.; Mr. J. S. Chater, Lond.; County Borough of Londonderry, Clerk of; Cumberland Infirmary, Carlisle, Secretary of; Dr. W. H. Corfield, Lond.; City of Sheffield, Clerk of; Mr. J. B. Cameron, Lond.; City Asylum, Gosforth, Secretary of.

D.—Dr. J. M. Day, Dublin; Mr. R. Dane, Sandown; District Messenger and Theatre Ticket Co., Lond.; Mr. E. Darke, Lond.; Messrs. A. De St. Dalmas and Co., Leicester; Mr. E. R. Dale, Salisbury; Devonshire Hospital, Buxton, Secretary of.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Address in Medicine:

MEDICINE AS A SCIENCE AND MEDICINE AS AN ART.

Delivered at the Annual Meeting of the British Medical Association held at Ipswich on August 1st, 1900,

BY PHILIP HENRY PYE-SMITH, M.D., F.R.C.P. LOND., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—It has sometimes been disputed whether medicine should be regarded as a science or as an art, but there is no doubt that the original meaning of "medicine," and of the corresponding term in other languages, is the art of healing. Medicine is so defined by Aristotle, and the art of curing, to which we may add the art of preventing, disease has all the characters of an art. It depends upon experience and skill, it deals with individual cases, and the perfection it aims at is practical, not speculative—the knowledge how to do and not the knowledge how things happen. Nevertheless, as practical navigation is founded on astronomy, meteorology, and physics, and as the art of agriculture rests on botany, geology, and vegetable physiology, so the art of medicine depends on the science of pathology, the practice of physic on the principles of physic. On the one hand, then, we must never forget that we practise an art. We must never allow theories, or even what appear to be logical deductions, or explanations however ingenious, or statistics however apparently conclusive, or authority however venerable, to take the place of the one touchstone of practical medicine, experience. We must never treat the disease without considering the patient, for the art of healing is the art of healing individually. Nor need we wonder if vast knowledge, profound learning, and the best scientific training sometimes fail to make a successful practitioner, since, besides adequate knowledge to save us from gross blunders and a strenuous endeavour to do our best for each patient, however uninteresting the case or however irksome and unrewarded our toil—besides these first requisites for our art there is ample room for those personal qualities which ensure success in every department of life: for power of observation and insight, for the personal influence by which a strong character will secure obedience and inspire hope, for the judgment which divines what kind of remedies are suited to each patient, what kind and of what strength, and for the sympathy which puts one in the patient's place and not only meets, but anticipates, his wants.

If, however, medical science without art is inefficient, medical art without science is not only unprogressive but almost inevitably becomes quackery. As soon as we treat our patients by rule of thumb, by tradition, by dogmas, or by metaphysical axioms we do injury to ourselves as well as to them. The bone-setter who is ignorant of anatomy and the wise woman who cures by charms are not more irrational or less successful than was the physician of the seventeenth century who, in obedience to the doctrine of signatures, advised an infusion of roses for hæmorrhage, and saffron for jaundice, and lungwort for consumption, or the astrologer who prescribed salts of silver, iron, lead, or mercury in accordance with the horoscope of the patient and the planet under which he was born. Not less mischievous, and, in the true sense of the word, unscientific, were the systems of medicine known as the "iatromechanical" and the "iatrochemical," which in their turn had their vogue. The Brunonian system, explaining all diseases as due to laxity of fibre, was no better; for indiscriminate use of "corroborants," or, as they would now be called, "tonics," is as irrational as that of hydropathy, of alcoholic stimulation, or of electricity. There is no such thing as a tonic or strengthening medicine. The only source of strength is oxidisable food, and bitter medicines can only give strength by improving appetite and digestion. The last of the systems of medicine founded on a dogma is homœopathy, of which the theoretical absurdity is somewhat concealed by the more obvious nonsense of infinitesimal doses. It, like other systems which preceded it, is not a rival to rational medicine, it is not a mistaken answer to a legitimate question but an attempted solution of a problem which does not exist and an attempted answer to a riddle which has no solution.

Apart from these exploded systems of treatment our profession has often suffered from lack of the scientific, inquiring, sceptical spirit and has often been led too easily by authority, by tradition, and by fashion. The reckless abuse of venesection in the last century and the former half of this century led to almost complete disuse of a valuable means of treatment and the misuse of mercury in the treatment of syphilis led to the denial of its unquestionable efficacy. Have we not seen the value of stimulants in a contest with fever lead to their indiscriminate use in almost every ailment? Has not the immense value of careful and thorough nursing led to its absurd exaltation to an independent place—as if good nursing was anything more than an intelligent carrying out of the physician's directions? Has not the remarkable power of electrical stimuli led to a blind, unscientific, and mischievous employment of this remedy as if it had some mystic power apart from its demonstrable physiological effects? May we not say the same of hydropathy, of massage, and of hypnotism? It is significant that the irrational exaltation of any of these particular modes of treatment into a panacea, while it begins in want of scientific intelligence, invariably ends in imposture and deceit. Our only safeguard against the spirit of quackery and the deserved loss of public confidence in the profession which it brings with it is continued recurrence to the scientific basis on which the practice of medicine rests. Our art is most satisfactory and efficient when most closely resting on science. The surgeon is continually guided by anatomy and mechanics in dealing with injuries and deformities. The physician is often able to apply his knowledge of chemistry and natural history to the direct and satisfactory treatment of disease. In general, medical science justifies itself in the same way as astronomy or chemistry by its predictions coming true. In particular the detection of plumbism, the diagnosis and cure of scabies and ringworm, the treatment of poisons by chemical antidotes, and of specific diseases by attenuated inoculations, are all instances of strictly scientific medicine. Nor can I refrain from citing the most recent and one of the most remarkable advances of our science in the discovery of the origin of malaria. This heavy tax upon national as well as individual vigour and happiness has been known and treated from the dawn of medicine; but although by a happy accident its efficient treatment was discovered it is only lately that by the combined labours of scientific physicians, Frenchmen, Italians, and our own countrymen, the origin of the disease has been discovered, the mode of its transmission traced, and the diagnosis of its several forms established. We know that treatment of symptoms without a diagnosis is always unsatisfactory and frequently worse, but we know also that diagnosis must rest upon accurate knowledge of morbid anatomy and of the natural history of the disease. Scientific medicine based on observation and experiment is always practical as well, but empirical medicine, whether based upon fanciful speculation or working by blind rule of thumb, is the most impractical thing that can be.

PREVENTIVE MEDICINE AND ETIOLOGY.

That important and constantly growing branch of medicine which deals with the prevention rather than the cure of disease depends no less upon science, for tracking the dependence of one event upon another is the essence of inductive science. All efficient measures for the preservation of health, whether by individuals or communities, rest upon exact knowledge of the natural course of diseases. In fact, disease may be defined as the reaction of the human organism under conditions which make for its destruction. We must never forget that no irritant will cause inflammation in a lifeless skin; that no bacteria can produce fever without a nervous system to play upon; that no meal, however Gargantuan, and no potations, however deep, can produce their wonted effect without a stomach to react. The infection of small-pox, of diphtheria, or of tubercle exerts a very different influence upon vaccinated or unvaccinated subjects, upon one who has received and one who has not received the prophylactic serum, upon an organism which is predisposed to, or which is refractory against, the invasion of the enemy. How closely natural science is related to preventive medicine

is shown by the history of Jenner who was a naturalist, and of Pasteur who was a chemist. How dependent we are upon science is well illustrated by the history of myxœdema. The cretinoid condition in adults which was discovered by the clinical acumen of Sir William Gull, unintentionally produced by the surgical skill of Professor Kocher, and reproduced in animals by Mr. Victor Horsley, is now cured by the eminently scientific method due to Dr. G. R. Murray of Newcastle and to Dr. Hector Mackenzie of St. Thomas's Hospital. Such examples of accurate tracing of causation by observation and experiment admonish us to give up the perfunctory explanations which so often do duty for investigation. If we ascribe every inflammation to cold or if we acquiesce in the popular ascription of disease to overwork, mental strain, and the nervous tension of modern life, we shall make no progress in true etiology. I see many patients suffering from idleness, but few or none suffering from hard work. "Nerve prostration" from "worry" and "brain-tension" generally proves to be a decent veil to the effects of gambling and drink. Modern life is easier, safer, and smoother that it was 100 years ago. Our young men and maidens are healthier, stronger, better grown, less emotional, less hysterical, and sounder in mind and body than their great grandparents. I venture to think that the duty of a physician is not to flatter the selfishness of neurotic patients, but to inspire fortitude and to prescribe regular and steady work as the best cure for a thousand nervous ailments.

As another point in scientific etiology, suffer a warning against the assumption that because many diseases are now proved to depend upon the presence of bacteria this must be true of all. Science does not anticipate but waits for proof. We have complete scientific evidence, according to the criteria so well formulated by Koch, of the absolute and constant cause of anthrax, of relapsing fever, of tubercle, and of several other diseases in both men and animals; but we must not forget the preliminary difficulty of identifying the specific bacillus as in the case of enteric fever and diphtheria, or the difficulty of finding one of the lower animals which is susceptible to the disease as again in the case of typhoid fever and of cholera, or the difficulty of the same anatomical and clinical conditions being produced by different organisms as in the case of pneumonia and ulcerative endocarditis. Moreover, while in some diseases which are undoubtedly infective and specific no constant pathogenic microbe has yet been determined—as in typhus fever, measles, small-pox, and syphilis—we have, on the other hand, in the case or leprosy and of lupus examples of disease unquestionably specific and bacterial in origin, but very unlike other infective maladies in their clinical course and natural history. At present it is surely undesirable to speak of "the undiscovered microbes of rheumatism." Science has to do with proved facts alone, and our language should never outrun our knowledge.

PROGNOSIS AND STATISTICS.

Another important branch of medicine—prognosis—depends as an art upon experience and insight. In making an individual prognosis shrewd observation is needed, and in this, of all branches of our art, it is true that—

> "Old experience doth attain
> To something like prophetic strain."

Yet here also rational prognosis rests on the science of statistics.

It is to Louis and the French School of the second quarter of this century that we owe the application of this important method for learning the natural history of disease—a method which not only supplies a foundation for prognosis but also a criterion of treatment. There are, however, many pitfalls in deducing conclusions from statistics. The morbidity or incidence of a particular disease upon the whole community is often confused with the mortality or the fatal cases of it compared with the population, and this last is confused again with the case mortality. The return of deaths from a certain disease in a town or kingdom has been applied to the population which existed eight or nine years before. The success of treatment of a disease occurring in barracks—that is to say, among picked subjects, all in early manhood, under strict discipline, and sent to hospital as soon as they are unwell—has been compared with that of other measures carried out in totally different circumstances. As examples of statistical misuse take these facts. The numerical returns of the lying-in charity of a London hospital led to the conclusion that more women were delivered of a second child than a first. A physician to inspire confidence in an anxious patient assured him that the mortality of the complaint from which he was suffering was only 1 per cent., and in answer to the further inquiry whether he had seen many cases, said, "Yes, I have looked at my note-books and find that I have seen 99, and they all recovered."

Apart from the corrections and limitations of statistical science we are sometimes in danger of forgetting that to be of any value statistics must be based upon cases which are both numerous and accurate. A small number of cases is useless. It led to the conclusion that myxœdema was peculiar to women and that insular sclerosis was rare in men. It was only after hundreds of cases had been observed that we learnt that infantile paralysis sometimes befalls adults and that osteo-arthritis may occur in children. This defect is remedied by time, but the defect of inaccuracy is without remedy. If diagnosis is perfunctory or careless or nomenclature is arbitrary and inconstant the more cases observed the less do they teach. It is disappointing, after the immense labour, time, and trouble devoted to the compilation of the official nomenclature of diseases of the Royal College of Physicians of London that although adopted in the navy and the army and by the Registrar-General it is constantly neglected, not only in conversation, but in systematic treatises. How can statistics be anything but misleading when made up of cases of one and the same disease under such different titles as "chronic rheumatism," "rheumatic gout," "rheumatoid arthritis," "arthritis deformans," and "osteo-arthritis"? Of what value are statistics when such different diseases as acute lobar pneumonia, broncho-pneumonia of children after measles, pulmonary tuberculosis, cirrhosis, and septic suppuration of the lung are all labeled "pneumonia"? One difficulty is put in the way of the practitioner in making an accurate return by the well-meant, but I think in practice unfortunate, provision for returning a primary and a secondary cause of death. Sometimes this corresponds to facts and gets over a difficulty; but if a patient dies from enteric fever there is nothing gained by adding congestion of the lungs as the secondary cause, still less do we learn from a return of "primary cause, a chill; secondary cause, debility." As a matter of fact, in looking through hundreds of death-certificates one arrives at the valuable conclusion that a frequent cause of death is "exhaustion" or "cardiac failure."

Another and opposite mistake is often made by attempts at too great precision in diagnosis. To say that a man died from apoplexy or from paraplegia is to state a fact within any competent practitioner's knowledge, but in the absence of a post-mortem inspection to say that he died from cerebral hæmorrhage or from myelitis is not a fact but a more or less doubtful inference. It is surely better to be satisfied with a statement that there were ascites and enlargement of the liver when the cause of enlargement is altogether uncertain than to be more exact and less true. I have again and again seen diseases the existence of which no experienced physician would assert without a necropsy returned as if they were common and easily recognised conditions—"pernicious anæmia," "syringomyelia," or "cancer of the lung." It would, I venture to submit, be a great improvement if the return of one cause of death only were demanded, if certainty and definite statements were aimed at rather than speculative minuteness or vague generalities, if a query were allowed to qualify deductions as distinct from observations, if the fact or the absence of a necropsy were always stated, and lastly, if the authorised nomenclature was always used.

EXPERIMENTS IN SCIENTIFIC MEDICINE.

There is one aspect of scientific medicine so important that it must not be omitted—the necessity of experiments for the progress of pathology and through it for the prevention and cure of disease. It requires no argument to convince anyone who is the least acquainted with the principles of inductive science that experiment is no less necessary than observation. In physics and in chemistry this is obvious and is universally acted on. The same method is indispensable for the progress of animal and vegetable physiology, and to such practical applications of science as engineering, agriculture, and medicine. Nor can experiments be restricted to rare and solemn occasions. They must be carried on in large numbers by many different experimenters and under every variety of condition. Any attempt to abolish, to check, or to limit this experimental

work is, in the degree that it is successful, fatal to progress. Happily it can never be successful, for the impulse to increase knowledge of the works of creation is too deeply implanted in men. Investigation must and will go on by the only path which it can follow. The method which was preached by Francis Bacon and followed out by his great contemporary William Harvey, which was continued by Lower, Hooke, and Mayow in the early days of the Royal Society, and by Aselli, Malpighi, and Haller, by Hunter, Hewson, and Hales, by Edward Jenner, by Sir Charles Bell, by Johannes Müller, by Claude Bernard, by Ludwig, and by the many eminent physiologists and pathologists in Germany, in France, and throughout the civilised world—this method of investigation is absolutely necessary for the progress of our art. As its objects and methods are better understood it will secure the enlightened patronage of all who desire the diffusion of human knowledge and the further spread of human happiness. Fortunately this very progress of science has brought with it the removal of the one grave drawback which every right-thinking man must have felt to the benefit we reap from these experiments upon living animals. Inflicting pain upon the humblest of God's creatures is repugnant to our feelings, though no one (unless maintaining a thesis) would contend that it is wrong to exact the most painful efforts, or even the death from exhaustion, of a horse in order to carry help to a human being. The discovery of ether, chloroform, and other anæsthetics and the improved methods that we owe to the genius of Lord Lister have not only relieved the surgeon of the most repulsive part of his duties but have relieved the experimenter also. Except in the investigation of the action of new remedies or in the inoculation of infective diseases—both of which inflict discomfort of a limited degree and duration rather than anything that can be described as pain—the experiments of the laboratory, whether physiological, pathological, or therapeutical, are conducted without inflicting pain. The opposition to them has not succeeded and it is sure to diminish. However mistaken our opponents we are glad to find that there is even exaggerated jealousy to avoid anything approaching to cruelty. Our more candid critics may be assured that this legitimate object is already amply provided for.

THERAPEUTICS AND SCIENCE.

Lastly, how far is the final end of our art—the cure of disease—directly dependent upon science? It rests, we know, upon that sure basis, but even in its practical carrying out we are bound to take with us a scientific spirit. The administration of digitalis for cardiac dropsy, of mercury for syphilis, and of thyroid extract for myxœdema is as truly scientific as prescribing a chemical antidote for poison or nitro-glycerine for angina pectoris, for it rests on a sure basis of observation and experience. But because in many cases we cannot as yet explain how remedies act we should not prescribe them without watching the effects of the experiment. The foolish cry against hospitals as "places where they experiment on patients" is meaningless just because it is true. Every prescription given, every operation performed on rich or on poor, is an experiment and ought to be watched with critical and scientific eyes. Here let me say that our practice is often ineffectual, not for want of an accurate diagnosis or of adequate means of treatment, but merely for want of the needful treatment being thoroughly carried out—a want which inevitably prevents success and therefore leads by a vicious circle to scepticism and want of thoroughness on the next occasion. A man who believes everything he is told of the action of remedies not only in the serious treatises of Garrod, or Wood, or Brunton, but in the partial assertions of advertising druggists, is sure to be unsuccessful, and, beginning with credulity, is apt to end in unbelief of such remedies as digitalis, and mercury, and opium. Such a man will prescribe and will never see that his prescription is carried out, and by the habit of giving multifarious mixtures of drugs in ineffectual doses he will allow what he has ordered to be taken three times a day for a fortnight to be really taken twice or only once a day for a week. He will prescribe exercise or lying down, abstinence or feeding, and never see that his directions are carried out. Who shall blame the patient if he ceases to believe in remedies to which the physician obviously attaches no importance? If we would sometimes prescribe no drug at all, but insist on abstinence from certain articles of food or drink or on more frequent or less frequent meals, on regular exercise or absolute rest, should we not secure more obedience from our patients when we prescribe really necessary drugs—just as a clergyman who desires to get a liberal collection would do wisely to begin by insisting on the sin of giving to charities which one believes to do more harm than good? How can we expect success in treating an obscure nervous affection if we apply galvanism to the spine without making sure of any physiological effect, nay, sometimes without making sure that a current is passing through the electrodes? or if we send a patient to drink the waters of such and such a fashionable watering place without remembering that there are two or perhaps three springs, one of them inert and the other perhaps injurious? What success can be anticipated if we order ointment for a weeping eczematous patch where it floats on the secretion and never reaches the inflamed tissue? or if we prescribe a lotion to be applied twice a day to skin well protected by its sebaceous secretion? We all know this half-hearted ineffectual mode of action in every-day life—we all know the man who wipes his shoes as a ceremony but never looks to see if he has got rid of the mud, the groom who feeds his horse but never sees whether the oats are eaten, and the nurse who washes the baby and still leaves wet places. Now much of this weak and therefore useless treatment comes of the indolence to which we are all prone and against which we must struggle as a temptation, but much of it, I am sure, is the offspring of incredulity which again springs from half-belief in quackery and imposture. Again, our ineffectual treatment often depends upon want of thorough diagnosis. Until we make up our minds whether a certain eruption is psoriasis or a scaly syphilide we shall never deal with it effectually. If we only suspect syphilis we shall give our remedies in too small doses and relinquish them if we do not see immediate benefit; whereas, if our diagnosis is real and thorough we shall use our remedies with confidence, increasing the doses, varying the form, but always persevering until we obtain the result we aim at.

Another source of failure in therapeutics is the legion of new remedies of which the biographies and eulogiums fill our waste-paper baskets and light our fires. It is astonishing to find apparently rational men forsaking the remedies which have been proved effectual by the experience of long past times and of every civilised nation to take up with drugs the very composition of which is often unknown, the use of which they have never learned, and of which the value rests upon the interested or credulous assertions of those who try to sell them. It takes a man long years of practice to learn how to prescribe opium. Why throw away this priceless knowledge to dabble in quack remedies the very praises of which inspire distrust? New remedies are, no doubt, discovered from time to time; in this generation we have had several, and all probable claimants should be tested in pharmacological laboratories and in hospital wards. But I am speaking of drugs which have never passed either of these tests. Surely in this age of advertisements which disfigure and defile the beauties of land and sea, of town and country, of literature and art, the most credulous must be convinced that costly and pertinacious advertisement is evidence of the lack rather than the possession of genuine worth. No, so far from our profession being carried away by this noxious habit let us hope that we may not only stamp it out from among ourselves but spread our own standard of conduct to other pursuits, until some day an honest tradesman shall be ashamed to push his sales by degrading self-laudation and the wealthy manufacturer shall shrink from offending the eyes and deafening the ears of his fellow-creatures by scribbling his name on blank walls and screaming it in every street.

In another popular branch of treatment it seems very desirable that the scientific spirit should be somewhat more freely admitted—I refer to treatment by baths and waters. That both are valuable modes of treatment no one will deny, but will anyone be so bold as to assert that it makes any difference whether our patients take a bath of water heated as it comes from the soil or heated to the same degree in a kettle? Who would pretend that so many grains of laxative or alkaline salts will act differently when occurring in natural solution and when dissolved in the same proportion in the druggist's shop? That benefit is obtained by change of air and scene, by early hours, regulated rest and exercise, and copious draughts of water is beyond dispute, but it is surely a pity when instead of rational explanation of our treatment our patients are deceived by unscientific and more or less untruthful statements.

Is it not a pity for so many of us to prescribe the made-up pills and mixtures offered us by wholesale manufacturers

instead of our own combinations? It leads our patients to ascribe their recovery, not to our skill, but to this or that "cure," and would it not be an excellent task for this great Association to set some of our skilled analytical chemists to strip the veil from mysterious remedies and tell us the exact composition of the many patent medicines some of which are inert and some injurious?

SCIENTIFIC MEDICINE AND ITS WAGES.

Finally, we may ask whether scientific medicine obtains the recognition that is its due at the hands of the public. I believe that on the whole it does, or if in any degree it fails that the failure is due to ourselves. We cannot expect that any but the most educated and enlightened should look at our science or our art from a rational point of view. The popular notion of a medical man among out-patients is a man who has got some wonderful stuff in a bottle which will make them well. The more educated patients suppose that, knowing what is the matter with them, or as we say, having made their diagnosis for themselves, their first business is to choose the practitioner who has devoted his exclusive attention to the malady of which they suppose they are the subjects, or if they chance to suffer from what they call a "complication" of diseases they will consult a "heart specialist" to cure palpitation, a "throat doctor" to cure hoarseness, and a rising young surgeon at "a special hospital for diseases of the knees" to cure weakness in that joint; and if they should find no relief after these consultations—

"Flectere si nequeo superos, Acheronta movebo"

—they denounce legitimate medicine as useless, and go to the lowest impostor, and will afterwards tell their friends that after being "given up by the faculty" they found instant and miraculous relief from a single box of wind pills, a galvanic belt, or a pad of oriental herbs worn on the pit of the stomach. The fact is that we cannot expect that our patients should understand the scientific basis of medicine, the meaning of etiology, or the possible degree of efficiency of treatment. What they frequently ask of us is to allow them to continue the very course of life to which we have laboriously traced their symptoms and to give them some medicine which as if by a charm will break the inevitable sequence of cause and effect. They are slow to understand that this world gives nothing for nothing, and that we can only subdue Nature by obeying her laws.

There is, indeed, only one way in which we can obtain what we call our just recognition. Our services, however great, are services to the individual not to the community. It is therefore absurd for us to expect the honorific or the more solid rewards justly assigned to statesmen, to generals, or to judges; but from individuals we may expect—and I venture to say that as a rule we receive—the trust, the honour, and the gratitude which we have earned. Few of our patients will ever understand our principles or our methods, the reason for our successes or the explanation of our failures; what they do understand is personal character, honesty and sense, kindness and sympathy, and liberality and benevolence to rich and poor. These are the qualities which have always gained and still gain the respect of our fellow-men; and I venture to say that there is not a town in the three kingdoms where such respect is not widely and deservedly enjoyed by our profession. Go to any cathedral or almost to any parish church in England and you will see tablets bearing witness to that respect. If such men do not receive all the money they deserve they have money's worth. They spend their lives in constant exercise of the powers of the mind guided by the best feelings of the heart—a sure path to happiness. They find constant interest in their daily work, and when their work is over and the medical man becomes the patient—as we all shall one day—they can look back on a life spent in the service of God and man with gratitude to both.

ACCOMMODATION FOR INFECTIOUS DISEASES AT BRISTOL.—The Health Committee of Bristol propose to submit to the Town Council a scheme for increasing the accommodation for infectious diseases. At present 147 beds are available, which is an average of one bed for 2300 of the population. The Health Committee suggest the extension of Ham Green Fever Hospital by the addition of the buildings originally intended and in the meantime temporarily to re-open Clift House, Bedminster, as a hospital in case the present hospital should not afford the necessary accommodation.

Address in Surgery:

THE SURGEON IN THE NINETEENTH CENTURY.

Delivered at the Annual Meeting of the British Medical Association held at Ipswich on August 2nd, 1900,

BY FREDERICK TREVES, F.R.C.S. ENG.,

SURGEON EXTRAORDINARY TO H.M. THE QUEEN; SURGEON-IN-ORDINARY TO H.R.H. THE DUKE OF YORK; CONSULTING SURGEON TO THE LONDON HOSPITAL.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—The honour of being selected to address an Association which represents not only in numbers but also in dignity and repute the medical profession of this country is an honour of such a kind that I feel it can only be belittled by any expressions of gratitude I am able to command. I will do no more, therefore, than sincerely thank you for bestowing upon me a great distinction, and at the same time remind myself of the words of Goethe that "it is easier to bind a wreath than to find a head worthy to wear it." I am fortunate also in the circumstance that the occasion for the giving of this address should coincide with the concluding year of the nineteenth century. This century has been without a parallel in the history of human culture, and so far as the art of surgery is concerned has embodied an advance in principle and in practice which has been no other than revolutionary. I do not propose to attempt a review of the progress of surgery during the last 100 years. That work has been already done by abler hands. I would venture rather to deal with the progress of the surgeon himself during this period and with the advancement of the individual as an exponent of a grave profession.

There is little difficulty in fashioning a picture of England as it was 100 years ago. A sympathetic literature has left us with ample records of the men and women of the time and of the scenes they moved among. These records are rich with the littleness of personal affairs and are made living by the very gossip and petty commentaries of those who constituted society when the century was young. The life in England then was largely life spent in the country, in sleepy villages, and in sober self-esteeming county towns. The conditions were yet immature which led men to herd together in ever-extending cities and to swarm around oases of blackened chimneys and restless furnaces. Travelling was a luxury limited to the few. The many were content to live and die within sight of fields and spires which had been familiar from babyhood. They were apparently content to keep to their own stations in life, to take their notions of dignity from the squire and their conceptions of religion from the vicar, and to be satisfied with such excitement as was afforded by harvests and market days, by the movements of the locally great, and by the achievements and misdoings of their neighbours. In many a town it was no little event when the coach from London lumbered through the cobbled streets, or when a gang of pressed men marched by on their way to the sea, or when some soldier home from the wars made the little alehouse lurid with tales of arms and tragic lands. These simple folk were comparatively free from the fever of social ambition, from the almost savage conflict of modern commerce, and from the bewildering hurry of events which compass the peace of later times.

London was then not one-fourth of its present size; the great city ended towards the west at Sloane-street and beyond were quiet fields and meadows intersected by foot-paths, certain of which led to the hamlet of Kensington and the little riverside village of Chelsea. The lover of solitude would have found seclusion in the wide open country through which ran the Edgware-road. Paddington was still in the fields. Game could be shot about Westbourne Green and around the isolated farmhouse which marked the present settlement of St. John's Wood. Few would have cared to venture after dark across the bare fields of Battersea or to traverse the expanse of open land which stretched to the north of Tottenham Court. No railway terminus flaunted its hideous structure in the city's midst, and neither omnibus nor cab nor tram-car invaded the narrow streets. There was no telegraph and no telephone,

The postal system was without form and void. The gayest streets were lit by oil lamps and the gloom by night was only equalled by the dirt by day. It was not until 1829 that the omnipotent policeman appeared upon the scene, and his early experience of the city's traffic was concerned with sedan chairs and cabriolets, with gaudy coaches and creeping wains, with linkboys and running footmen. It was not until 1821 that the English Channel was crossed by steamboats and that the hoys and coasting sloops, the dignified frigates and the stately East Indiamen began to vanish from the sea. Education among the mass of the people was a matter of little account and was to a great extent actually non-existing. The average man of the middle-class was quite content with a degree of learning which would do little more than satisfy the demands of a modern School Board.

As to the surgeon in those days, he was but a sorry element in social life. In the great towns and cities there were esteemed practitioners of surgery who were eminent by reason of their scientific work and their successful practice, but their numbers were few. At the commencement of the period under notice London was the centre of surgical activity, and the prominent exponents of the art at that time were John Abernethy, Henry Cline, Sir William Blizard, Sir Everard Home, Sir Astley Cooper, William Lawrence, and Charles Aston Key. The great John Hunter had died in 1793, having accomplished a work which marks an epoch in British surgery. In the provinces the most conspicuous surgeons were Edward Alanson of Liverpool and William Hey of Leeds, while in Edinburgh the position of the leading operator was held for many years by John Bell. A little later in the century we find among the names of prominent men in England those of Sir Charles Bell, Sir Benjamin Brodie, and the ingenious and learned Benjamin Travers. At the beginning of the century surgery on the continent was represented by such men as Sabatier, Deschamps, Boyer, and Larrey in France, Scarpa in Italy, Langenbeck, Chelius, and Dieffenbach in Germany, and Warren and Physick in America.

The surgeon or common practitioner in the village and town in these early days has been depicted by many writers. Possibly the most precise of these was Smollett who was himself in turn an apprentice, an assistant, a surgeon's mate, a practitioner, and a graduate in medicine. Smollett died in 1771. The account he has furnished of the leech of his time is tolerably discouraging. We find him an ignorant, illiterate, sordid creature, not above the allurements of money-grubbing and not without suspicion of dishonest practices and of a leaning towards the bottle. He was to a large extent a mere retailer of physic and in the public eye he ranked with the quacks and nostrum-sellers with whom he competed. There was probably some excuse for a writer who, in a discourse in the *New Monthly Magazine* for 1828, speaks of the general body of surgeons as a "cringing pulse-feeling race." Smollett's description could not have been true of all his brethren and there is no doubt he wrote with the bitterness of an unfortunate experience. Still, there can be little question that Launcelot Crab represented a type not yet extinct when the century began, and he must be taken as a forerunner of the cultured and esteemed general practitioner of the present day.

I.—THE SURGEON AS AN ADVISER.

In noting the advances made by the surgeon during the century the first matter which may be dealt with concerns his position as an adviser to his patient. In reviewing this subject one cannot fail to be immediately impressed by the paramount influence which exact knowledge—or *a fortiori* the want of exact knowledge—has had upon the attitude of the medical profession.

It is obvious that the progress of any science is to be measured by the amount of absolute truths which may have been accumulated at a given time. The lack of knowlege, the mass of things unknown, represent merely a void to be filled. In the development of the science of medicine the element of the unknown has not remained so negative a factor, but has, on the contrary, proved to be a stimulus for a very luxuriant invention, the products of which have been tabulated as facts. There is no science outside our own in which there has been during the stages of development such an extreme disproportion between the amount of knowledge professed and the amount proved ultimately to be exact and sound. As an example of this may be cited the "humoral" system of pathology which, in spite of its ancient origin and its more or less obvious foolishness, held a position in medicine for centuries and struggled on, as a distorted and dying creed, even into modern times. This system, in its barest features, asserted that four cardinal humours occupied the human body and that practically all diseases, and certainly all tumours, were due to disorders of certain of these fluids. The pathology of this system was precise, dogmatic, elaborately classified, and full of detail. Upon it all treatment was founded and yet the whole of this precious system was a mere daring fiction, an ingenious fancy, the product of an impudent and unscrupulous imagery. The reason for all this lies more with the sick man than with the man of medicine. The sick man requires absolute exact knowledge from his doctor. He will accept neither possibilities nor doubts nor confession of ignorance. He will accept such from his lawyer and from his man of business, but not from the man who attends him in illness. It is no matter of wonder that in the past the physician has made good by fiction what he lacked in fact. The demands of the patient have been hopelessly beyond any powers of supply, and the deficiency has been furnished by the products of invention. It would seem that the less the man of medicine knew the more he invented and the more diligently he hid his little light under the bushel of a ceremonious and mystery-making treatment. The judicial wig, the academic ruffle, the gold-headed cane, the reflective snuff-box, and the Socratic air all made an effective covering for the few poor bones which formed the skeleton of his knowledge. It thus happens that a good deal of the pretence and humbug with which medical practice has been associated in the past has been forced upon the practitioner by the demands of unreasoning people. With such people the surgeon in the early part of the century had more largely to deal than he has to do at the present day, and yet his stock of knowledge could seldom meet the demands even of the reasonable. Hereby it came to pass that the puzzled man of medicine had to repudiate his ignorance, had to concoct such explanations and to construct such pathologies as could meet the sick man's inquisitiveness, and at the same time give a semblance of reason to an empirical and tawdry system of therapeutics. His utterances were tangled and confused by conceits of his own invention. A false attitude towards his patient was unconsciously forced upon him, and the folly of his pretence to an unattainable learning was apparent to all but the simplest. As an adviser, therefore, he spoke not as one having authority, and his position intellectually is well illustrated by the endless lampoons and caricatures to which he was publicly subjected.

The surgeon of the present day, as an adviser, is in a position which is so greatly improved that it could hardly have been imagined by his forbears of 100 years ago. He has, in the first place, to deal with a more enlightened public, with patients whose education to a large extent enables them to appreciate the nature of scientific problems, and with whom it is possible to discuss difficulties and to own to lapses of information. In the second place, the additions made to surgical lore have been so substantial that in many departments surgery has reached to the status of an exact science. There is, indeed, no longer need to call upon invention to supply such gaps as still indicate the unknown. An intelligent patient is satisfied with the assurance that practically nothing at present is known of the nature and causes of cancer. Such assurance is at least as valuable as the information provided at the beginning of the century, when the inquirer would have been told that cancer was "a diseased hardness"[1] or a "scirrhous degeneration."[2]

We have perhaps not quite shaken off the poor vestments of mummery with which ignorance was clad nor rid ourselves of forms of speech which still pass current for sense but which are little more than sounding brass and tinkling cymbal. We speak assuredly of the "constitution" and of "states of the system" and of the "supporting of the system." We sanction such terms as "poverty of blood," "diminished vitality," and "sympathetic inflammation." We profess to believe in "tonics," in medicines the swallowing of which will give strength, in "galactagogues," in "alteratives," in "astringents," and in "cooling physic." We profess, moreover, to "strengthen the lungs" and give "tone to the stomach." The modern surgeon can well afford to dispense with all this empty verbiage, since he can base his opinion upon demonstrated facts and can express it

[1] Samuel Cooper's "First Lines," London, 1807.
[2] South's "Chelius," 1826-46.

in plain words, free from any of the embellishments of a literary masquerade. For many reasons this is well.

II.—THE SURGEON AS A MAN OF LEARNING.

The surgeon at the commencement of the century appears to have lacked most of what we now consider to be the essentials of the art, and we can only view with amazement the scantiness of his learning and the poverty of his equipment. He knew little more of inflammation than that it was represented by swelling, heat, redness, and pain. His knowledge of the causes of inflammation and of those dangers which follow upon open wounds was scarcely in advance of that professed in the days of Hippocrates. He had no glimmer of the possibilities of asepsis. He had no anæsthetics, no hypodermic syringe, no clinical thermometer, and no practical means of investigation in clinical chemistry. The very name "bacteriology" did not exist and the treatment of disease by prepared serums would have appeared to him as wild as the wildest therapeutic dream of ancient days. Although vaccination had been introduced in the last year of the eighteenth century the magnitude and nature of the principle it involved had not been appreciated. The microscope as an aid to diagnosis played no part in the equipment of the surgeon. He had neither laryngoscope nor ophthalmoscope and his acquaintance with otology, skin affections, and the diseases of women was at the best rudimentary and indistinct. He had only rude mediæval orthopædic appliances and he knew nothing of the lithotrite or of the array of instruments which are now in daily use in connexion with ophthalmic, laryngeal, cranial, and abdominal surgery. It would seem, indeed, that there was little for him to do but to open abscesses and sow the seeds of chronic septicæmia, to excise tumours of the structure of which he talked much and knew little, to amputate limbs for diseases he could not mend, and to draw blood whenever doubt existed as to what was best to be done. Conservative surgery was not understood and was certainly not practised, and plastic methods of operation had no place in treatment. Lord Thurlow, in speaking against the Surgeons Bill in the House of Lords in 1797, declared, with some basis of truth, that "surgeons in this country are not respectable men, their pretensions are unjust and illegal because they are not a scientific body."

In 1800 a man could practice as a doctor without passing an examination of any kind. Indeed, one itinerant practitioner is reported to have assumed the title of assistant surgeon on the ground that he had served an apprenticeship to the crutchmaker of a hospital. The examination for the diploma of the Royal College of Surgeons was by *vivâ voce* only. There was no examination of patients and no dissection of the subject. Candidates were required to produce evidences of apprenticeship, of attendance upon anatomical and chirurgical lectures, of having performed dissections, and of having attended the practice of a recognised hospital for a period of six months. In 1813 the period of compulsory attendance at a hospital was raised to one year. The standard of knowledge, however, does not appear to have risen in corresponding proportion, for in 1822 the then President, Sir William Blizard, felt called upon to address the Court of Examiners on certain "tokens of remissness in teachers and of inattention in students" which had been forced upon his notice. He regrets that candidates are commonly ignorant of the situation of nerves and blood-vessels, of the disposition of the muscular fibres of the heart, gullet, and stomach, and of the diameters of the intestine. He further adds that "the deficiency of candidates in physiological information is far more remarkable" and enters into such detail as the following: "Often do we find them," says the President, "ignorant of the reasons why the ribs in inspiration are, from their figure and muscular connexion, moved upwards and outwards, of the systole and diastole of the heart, of the process and intention of respiration, of the nature and distinction of the pulse, of the distinct offices of divers muscles, of the figure of the lens and uses of the humours of the eye in vision." He concludes by deploring that there is a "correspondent darkness of mind relating to the symptoms, seat, causes, and rational treatment of diseases and injuries," and furnishes a catalogue of items with which candidates do not appear to have been commonly conversant, although the list presents such matters as the signs of fractures and dislocations, the symptoms of compression and of inflammation of the brain, the consequences of fractured rib, and the *rationale* of the symptoms of hernia.

At the commencement of the century there was, indeed, no systematised medical education. The training of the surgeon was paltry, casual, and inefficient. His preliminary education was miserably meagre. It was necessary that he should be able to read and write and pretend to some smattering of Latin. He became an apprentice, and in that menial capacity gleaned what he might from his master and from attendance upon sundry lectures. So far as hospital practice was concerned, his attitude as a learner was well expressed by the phrase, "He walked the hospital." The institutions which he thus attended for a period of six months were in a state of rude squalor as regards administration, sanitary arrangements, and nursing, and well deserved the abuse which was lavished upon them.

III.—THE SURGEON AS AN OPERATOR.

During the nineteenth century the surgeon as an operator passed through a rapid metamorphosis and has now reached at least the level of the unexpected. It may have been supposed that there is little to be learnt in the way of using a knife which had not been learnt during a period of over 1800 years, for there were surgeons before the Christian era. Yet time has shown that even in 1800 there was a technic in operating which was as little like the technic of to-day as are the slashes of a cutlass when compared with the studied movements of a foil. It may have been surmised that 20 centuries would have exhausted the methods by which a limb could be cut off. Yet in 1800 modes of amputation were in vogue which are now regarded as uncouth. It cannot even be said that the commencement of the century saw in use a ready and efficient means of checking bleeding, although that measure represents the most elementary of the surgeon's duties.

The operator of olden times certainly possessed many qualities which are now falling into abeyance and which cannot pass away quite unregretted. The success of his craft depended largely upon his daring, upon the alertness of his eye, the steadiness of his nerve, and the rapidity of his movements. He stepped into the arena of the operating theatre as a matador strides into the ring. Around him was a gaping audience and before him a conscious victim, quivering, terror-stricken, and palsied with expectation. His knife was thrust through living flesh and acutely-feeling tissues, and the sole kindness of his mission was to be quick. In spite of moans for mercy from gagged lips the knife had to move on its way steadily and, undeterred by struggles and bursts of hæmorrhage, the blade must needs pass without faltering or sign of hesitancy. There is less need for such qualities now. The dramatic element in surgery has gone with the men who unconsciously fostered it. The operating theatre of the present day has lost its horrors and has changed from a shambles to a chamber of sleep. The surgeon's hand can move with leisurely precision and theatrical passes of the knife are favoured only by those who have not yet learnt that mere brilliancy is no measure of success. It may be that the present-day surgeon is a loser in that he has less need for those dashing qualities which were essential to the operator before the days of anæsthetics; but, on the other hand, he has gained much in the direction of the sympathetic handling of his patient and in the culture of gentleness. It is little wonder if the older surgeon became rough and stern, if his sense of feeling became dulled, and if the sympathetic side of his nature suffered some suppression. Indeed, contemporary accounts are apt to represent the operator of pre-anæsthetic times as rough almost to brutality and as coarse both in his conduct and in his utterances. His language, it would appear, savoured of the cockpit, and the hasty flourishing of his knife led occasionally to unintended mutilations.

Within the compass of some thirty years the whole state of affairs has changed. Consideration for the patient and for the patient's sensibilities have become a matter of the first moment and the operator has learnt that his work is best done if done with gentleness and tact, and that haste and bluster, coarseness and coarse handling are out of place around the operating table. A striving after effect at any cost has ceased to be an element in the surgeon's work. Success is no longer to be measured by the number of minutes occupied in the amputation of a limb, but by the state of the patient many days after the measure has been completed. The triumph of the older surgeon was immediate and scarcely reached beyond the arena of the theatre. The triumph of the modern surgeon is deferred and is found in the operation ward and in the convalescent home. Still, the

fact remains that it is easier to be a surgeon of some degree at the end of the century than it was at the commencement, since in the earlier days the qualities needed for success in operating were rare and of a kind not readily to be acquired.

On passing more into detail one notices that beyond these general changes in the attitude of the operator there have been others which owe their existence to special advances in the surgeon's art. Prominent among these may be named: (1) an improved knowledge of anatomy; (2) a readier method of arresting hæmorrhage; (3) the employment of anæsthetics; and (4) the introduction of antiseptic measures.

1. *An improved knowledge of anatomy.*—Among the surgeons of the early part of the century there were many competent anatomists and not a few who could lay claim to be deeply versed in that science. Among the latter were such men as Astley Cooper and William Lawrence. Still, in the education of the average surgeon the study of anatomy did not play a prominent part. Anatomy was largely taught by means of public demonstrations. The teacher dissected and the student looked on, much as he did in the days when Rembrandt's great picture of Nicolaus Tulp and his pupils was painted. The knowledge required was scant and superficial and had little practical basis, and no methods of teaching existed which can in any way compare with those in vogue at the present day. The science of anatomy was well advanced at the commencement of the century, but it was not taught to the common student. Quain's "Anatomy," first published in 1828, contained a very sound account of the human body, although the whole work was then represented by a single small volume of 700 pages which was without illustrations. The facilities for acquiring a practical knowledge of anatomy were not only few but were hampered by many sordid difficulties. Anatomical schools were regarded with disfavour and were actively discouraged. They were viewed with unconcealed suspicion by the public and were surrounded by a ghoulish romance in which rifled graves and unseemly dealings with the hangman played a pungent part. Indeed, the teacher in an anatomical school found himself involved in a squalid and disreputable traffic, very uncongenial to any earnest man of science. Among the many qualifications needed for success in operating, a practical knowledge of anatomy as acquired by repeated dissection is conspicuous. Such knowledge as the surgeon needs is to be learnt not from books but from the patient use of the scalpel and forceps. The dissecting room is the surgeon's nursery. The tissues of the body are the material with which he works, and he must needs know them as the sculptor knows the marble he chisels and the potter the clay he moulds. It is no matter of surprise that the older surgeon often lacked confidence in operating, that he failed in initiative, and clung only to formulated methods, and that a departure from accepted lines was attended with fear and hesitancy. Ignorance encouraged in the rash heroic passages of the knife and in the timid an over-cautious and dangerous fumbling. And as to this it is probable that in pre-antiseptic days as much ill attended the nervous fingers which were creeping clumsily into the unknown as followed the reckless operator who essayed to draw his bow at a venture.

2. *A readier method of arresting hæmorrhage.*—At the commencement of the century the means employed for the control of bleeding were numerous and were represented by such familiar measures as the ligature, the sutures, styptics of many kinds, and the actual cautery. In applying the ligature the vessel was picked up by forceps and tied as at the present day. The instruments used were those of Dieffenbach, Assilini, and Liston. The older types of instruments were not readily applied, or at least required time in their adjustment. The bleeding from the vessel was not necessarily controlled by the forceps when in position. The general rule in amputation was to apply a tourniquet and to ligature the individual arteries after the limb had been removed. In the excision of tumours the practice was recommended of securing each vessel as it was divided. When it is remembered that operations were carried out without anæsthetics it will be understood that the older surgeon had an absolute terror of bleeding and was driven to undesirable shifts to avoid the need of facing it. He was indeed a coward where hæmorrhage was concerned, and there was reason for alarm when a conscious patient was struggling and showing signs of exhaustion and when the means for staying the stream of blood were slow of application. We find, then, that hæmorrhage was expected and that a liberal loss of blood was considered to be a necessary adjunct to every major operation. Tourniquets were employed freely and with considerable harshness. Raw surfaces were bathed with styptic solutions which were often destructive in their action or at least opposed to primary healing. The actual cautery with which to sear the bleeding area was in some request, and every well-equipped operating theatre kept its stove and its cautery irons in constant readiness. The least pleasant evidence of the surgeon's dread of hæmorrhage and of his inability to deal with it was afforded by the treatment of certain nævi in infants and children. These growths were strangled by ligatures which slowly cut their way through the skin and neoplasm assisted by a benevolent process of suppuration. A painful ingenuity was expended upon amplifications of this measure, the cruelty of which was but little mitigated by the introduction of chloroform. Allied to this procedure was the *écraseur* of later date. Its invention was due to Chassaignac, and it was freely used in England until quite recent times. It was employed for the removal of growths of various kinds, but its most baneful employment was as a means for excising the tongue. It is scarcely to be believed that within the period of the introduction of anæsthetics the tongue has been torn out of the mouth by means of a loop of hemp or wire which strangled it at its root. The *écraseur* will remain in the archives of surgery as the insignium of the incompetent and the timorous and will stand out as a blot in an otherwise bright period of progress and enlightenment. The shadow of this mediæval instrument has been slow to fade and as the ovarian clamp and the serre-nœud it clung about the confines of reasonable surgery and hindered the development of the operations of ovariotomy and excision of the uterus. At the present day the surgeon has little dread of hæmorrhage and the confidence he possesses is based upon good grounds. In the first place he makes larger use of the precautionary ligature of vessels. It has become a commoner practice to apply a temporary or permanent ligature to a main artery before a part supplied by that vessel is excised. This is carried out frequently in dealing with large and vascular tumours. In removal of the tongue, moreover, an excellent method is that in which a preliminary ligature of both linguals in the neck is carried out. In removing the uterus through an abdominal incision the question of hæmorrhage is disposed of by an early ligature of the ovarian and uterine vessels. A further example of this mode of anticipating bleeding is afforded by that method of hip amputation which is known as the anterior racket. Here the main vessels and even the main branches are secured before the flaps are cut, whereas by the older plan the vessels were severed with the flaps and were tied after the limb had been removed. In the second place the latter-day surgeon is operating upon an anæsthetised patient and can proceed with slowness and deliberation. The importance of this fact in connexion with the present subject cannot be over-stated. In the instances which have been just cited an excision of the tongue in a conscious patient would be greatly extended by the twofold operation in the neck, and whereas the amputation of the hip by transfixion occupied in able hands but a minute or so, the operation by the anterior racket is tedious and involves relatively much expenditure of time. Thirdly, the treatment of hæmorrhage has been to a remarkable extent simplified, if not indeed rendered complete, by the introduction of the pressure forceps of Sir Spencer Wells. These little instruments represent the most valuable addition which has ever been made to the surgeon's appliances. It is not uncommon in operations of a certain type to have 20 or more pairs of pressure forceps applied to the surface of the wound at one time. This represents a degree of possible bleeding which in the old days, when every vessel had to be separately tied, would have been replaced by actual bleeding of a fatal type. No instrument has brought with it so great an assurance of security or has done more to extend the area of safe operation.

3. *The employment of anæsthetics.*—The value of the anæsthetic and the radical and beneficent transformation it has effected in surgical practice call for no comment in this place. The changes that the discovery has wrought in the personality of the surgeon, in his bearing, in his methods, and in his capability are as wondrous as the discovery itself. The operator is undisturbed by the harass of alarms and the misery of giving pain. He can afford to be leisurely without fear of being regarded as timorous. To the older surgeon every tick of the clock upon the wall was a mandate for haste, every groan of the patient a call for hurried action, and he alone did best who had the quickest fingers and the

hardest heart. Time now counts for little and success is no longer to be measured by the beatings of a watch. The mask of the anæsthetist has blotted out the anguished face of the patient and the horror of a vivisection on a fellow-man has passed away. Thus it happens that the surgeon has gained dignity, calmness, confidence, and, not least of all, the gentle hand. Anæsthetics have, moreover, greatly extended the domain of surgery by rendering possible operations which before could have been only dreamt about, and by allowing elaborate measures to be carried out step by step. The introduction of anæsthetics has not only developed surgery but it has engendered surgeons. It has opened up the craft to the many, for in the pre-anæsthetic days the qualities required for success in operating were qualities to be expected only in the few. In the technique of established operations chloroform and its allies have led to advantageous changes. This is well seen in the case of amputations. In the olden days that method of removing a limb was best which was the most speedy. A prominent position was on this account given to the cutting of flaps by transfixion, a long narrow blade being used for the purpose. This rapier-like instrument required great skill in handling and in the grasp of the feeble it was a fearsome weapon. Muscles were sliced through in such a way that the widest possible section of their substance was often made. Vessels and nerves were, in like manner, cut almost in the direction of their long axes, and the resulting incision gave the maximum area of wounding. At the present day transfixion is abandoned and the murderous amputating knife has found its way into the museums of the curious. Muscles can now be severed at right angles to their length or in such a way as to secure the smallest possible surface of section. Vessels and nerves are cleanly divided in the same manner and the resulting area of the wound is reduced to a minimum. This difference in methods is vividly illustrated by amputation at the hip-joint.

4. *The introduction of antiseptic measures.*—Of the great work of Lister and of the introducing of the antiseptic treatment there is no call to speak at this time. When the century was young the touch of the operator was the touch of a tainted hand; the balm he poured into the wound was poisoned and he himself undid the good his science strained to effect. It is sad to think that behind the earnest man with the ready knife there stood a shadow which rendered hopeless his kindliest effort and which only too often proved to be the veritable shadow of death. The change has been great, and its greatness lies in its littleness, for it is bound up with no more than this: that the surgeon has learnt to be clean. The operator of days gone by would have turned with some petulance from the grand simplicity of the counsel to be clean. He ever sought some means of mighty bearing to rid him of the incubus of failure, and, like Naaman of old, he would have hesitated to dip in the Jordan of antisepticism to be free of his leprosy. The surgeon has not only learnt to be clean but he has become aware of the potency of little things. The demands of the antiseptic treatment have made him minutely careful, distrustful of any aid that he cannot control, and suspicious of any semblance of error. It is possible that the abandonment of the old easy order of things has been followed by a too slavish devotion to mere ceremonial. The remarkable and extravagant preparations with which some surgeons now approach an operation, the cleansings and the washings which precede the laying on of hands, smack a little of fetich worship and foster the cult of the surgical Pharisee. On the other hand, these performances, this "making clean of the outside of the cup and platter," seem to give assurance and to render the devotee thankful that he is not as other men.

IV.—THE SURGEON IN THE FUTURE.

Circumstances in the tendencies of to-day foreshadow to some extent what may lie buried in the future. The changes which have swept over the world of surgery have extended the possibilities of the art and have, at the same time, added a host to the ranks of those who practise it. Some 30 years ago the roll of such as could claim to be accomplished operators was very small. The greater deeds of surgery were limited to cities and the larger towns. The general practitioner seldom took up the scalpel except in minor necessities. Even in London the list of consulting surgeons was meagre. In the hospitals of the metropolis the number of operations performed in the year would be less than is now the quotum for a month.

But here at the close of the century the disposition of affairs is wholly altered. Where there was one surgeon there are now ten, and throughout the breadth of the land and to its utmost limits the work of the operator has extended. The more ambitious performances of surgery are no longer restricted to great centres but are carried out in the little town, in the cottage hospital, and even in the cottage itself. The general practitioner is laying claim to operate upon his own patients and is carrying out his intention in no hesitating manner. The days of the great operator, of the one man to whom all came who could, are rapidly passing away. Indeed, the practice of pure surgery, which was at one time limited to the prominent few, is now becoming common to the many. The man who excels conspicuously as an operator will always attain such eminence as his ability deserves, but the exclusiveness of the practice of operative surgery is quietly vanishing with the century. This change is well. It is a change that is inevitable. The democratic movement is the active power of the day, and that an oligarchy in the community of surgeons should be replaced by an earnest democracy is precisely in accord with the spirit of the times. In every great change there must—at first at least—be some undesirable developments, and it is impossible to deny that the wider distribution of the practice of operative surgery may lead to the occasional performance of major operations by men who are not justified, either by experience or by training, in undertaking them. Furthermore, there is, among the signs of the times, some evidence that the reaction in the matter of operative surgery is to some degree extreme and that we are in danger of passing from the policy of doing too little to the policy of doing too much. Operations we know were too few in the past, but there is some foundation for the impression that they are occasionally too frequent in the present.

One other matter which looms out of the future will suffice to bring this subject to a close. So many have been the artificial aids to clinical investigation which recent science has introduced that it comes to be a question whether the natural acumen of the surgeon will not deteriorate in proportion as he fails to encourage that particular learning which clings to the finger tips of all great diagnosticians. That there will be such a decadence is beyond doubt. The loss is to be deplored, for if there be one point of excellence which stands before all in the qualifications of the perfect surgeon, it is bound up in that refined sensibility, that critical perception, that inestimable cunning, which lies in the surgeon's touch.

Examples of the directions in which this loss will be felt come readily to mind. A considerable amount of skill, for example, is demanded in the examination of complex fractures, of lesions of deep-seated bones, and of injuries about joints. What was to be learnt of these troubles had to be acquired by a tedious manipulation demanding considerable refinement. The surgeon who has now to deal with such conditions can afford to dispense with a prolix examination and can submit the inquiry to a demonstrator of the Roentgen rays. The skiagraph, although its value is much exaggerated, embodies a substantial gain, but it is to be discounted by the loss of the great element in education which it is slowly replacing. An obscure tumour—to take another instance—presents itself and no longer is the surgeon compelled to trust to the acuteness of his inquiry and his patient review of all the physical details of the mass. For what his ready fingers may have learnt can be substituted the findings of the exploratory incision, the trocar, and the aspirator. Here once more an advantage is minimised by a loss. Or, again, an abdominal swelling is brought under notice. Its features are obscure, but much of the uncertainty of outline can be dissipated by a cultured hand which, with infinite patience and repetition, has learnt to construct a reality out of a shadow. It may be said that it is needless to persist in bringing this much elaborated means of inquiry to further perfection since the problem is at once to be solved by an exploratory laparotomy. By such little operation a great advantage is gained but an opportunity to add to one of the most refined forms of learning is lost. The value of the exploratory incision is beyond question, but among the signs of the times it is impossible not to notice a tendency to resort too readily to this means of solution. The Gordian knot, according to the legend, was ultimately cut, and it is a question whether the sum of human ingenuity would not have been substantially increased if attempts to untie the noose had been more diligently persisted in. In another example let it be supposed that a suspicious ulcer presents itself for diagnosis. In such case is it well to devote time

to a precise and tedious inspection of its edges and to a careful tactile examination of its base and to check what is discovered by results laboriously gained from like inquiries? Is it not simpler to take a scraping of the affected surface and to submit it to a microscopist, and thus to be spared a method of examination which, although it may not give final results, yet represents an opportunity of furthering a priceless accomplishment?

Finally, there are cases which present symptoms hard to interpret at any superficial inquiry. Is it worth while in such to undertake an exhaustive critical research and to submit the whole to a trained judgment? The quest would no doubt develop habits of observation and powers of weighing evidence; but the process is slow, and an inquiry carried out in a bacteriological laboratory will clear up all doubts and at the same time dispense with the efforts of a cultured sense. Those, therefore, who are concerned with the education of the surgeon of the future would do well to cherish still this ancient power and to foster a memory of the fact that surgery is, in its very essence, a handicraft, and that in all that he does the surgeon's great endeavour should be to make his own hands self-sufficing.

It is sad to think that this hardly-acquired faculty dies with the possessor of it, and never was this more vividly presented than it has been by the loss which surgery has sustained in the death of Sir James Paget. One can picture the great surgeon composed in his last sleep, and can see the once busy fingers lying lifeless on the white sheet, and then comes the wonder of the wealth of learning, at the exquisite cunning, at the refined sense which lay dead in the dead hand. No written book can hold a tithe of the dainty knowledge which had been mastered by those subtle fingers, and no record, however laboured or however loving, can tell of the power which once rested in that magic touch. An individual loss does not, however, hinder the general tide of progress. Advance in such a work as ours depends upon the uneventful work of the whole body and is only accentuated by the achievements of the prominent few. The movement is the movement of a multitude in which individuality is, at a distance of time, little to be distinguished and in which personal eminence contributes a smaller factor than the present is ready to acknowledge. Those who stand forth as the leaders of the advance are merely the elect of the common body and the representatives of a wide intellectual franchise. Even he who startles the world as a discoverer has often done little more than give expression to what was already nascent in the multitude. So as one great surgeon after another drops out of the ranks his place is rapidly and imperceptibly filled, and the advancing line moves on with still the same solid and unbroken front. The continuity of progress is undisturbed by the uncertainties of human life, and, as one writer has well expressed it—

"No work begun shall ever pause for death."

A CASE OF MENINGO-MYELITIS WITH BACTERIOLOGICAL EXAMINATION OF THE SPINAL CORD.

BY GEORGE R. MURRAY, M.A., M.D. CAMB., F.R.C.P. LOND.,

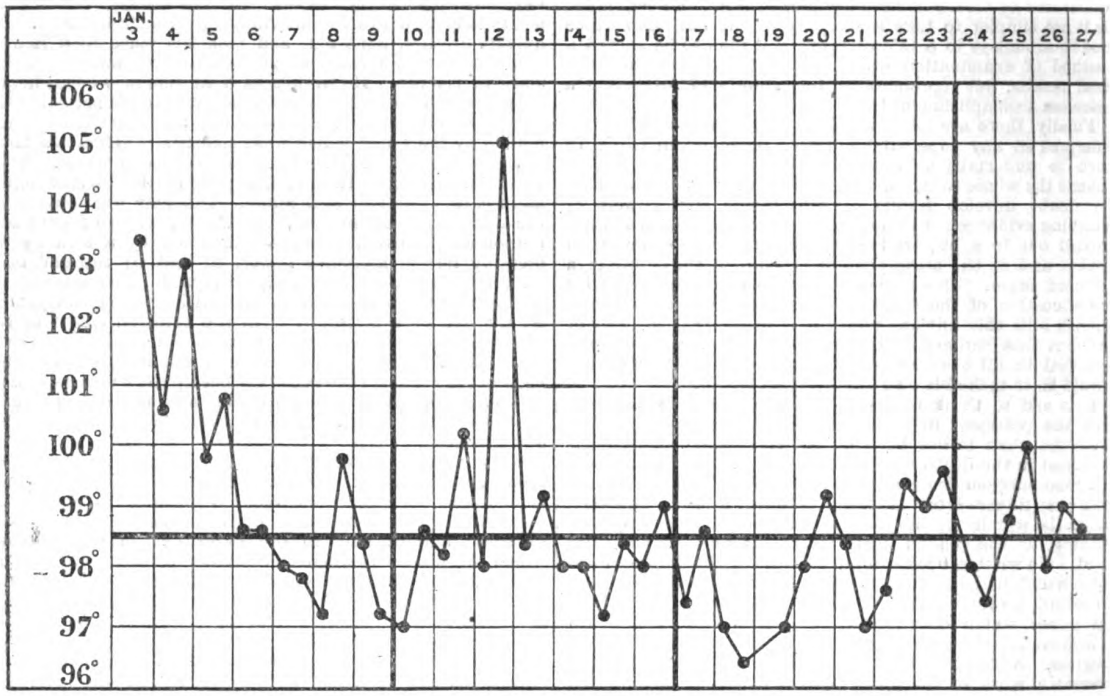
HEATH PROFESSOR OF COMPARATIVE PATHOLOGY IN THE UNIVERSITY OF DURHAM; PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE;

AND

W. HARDCASTLE, M.B. LOND., B.HY. DURH.,

DEMONSTRATOR OF BACTERIOLOGY IN THE UNIVERSITY OF DURHAM; RESIDENT MEDICAL OFFICER AT THE DISPENSARY, NEWCASTLE.

THE acute onset and rapid course of many cases of meningo-myelitis are very strong indications of the infective nature of the disease. Several cases have been recorded in which a bacteriological examination of the spinal cord and meninges has revealed the presence of a micro-organism endowed with pathogenic properties. The total number of such cases is small and so we consider that the following case is worthy of being published in spite of the incompleteness of both the clinical record and the bacteriological examination.



A single man, aged 29 years, was admitted into the Newcastle Royal Infirmary on Jan. 3rd, 1899, on account of complete loss of power and sensation in both lower limbs. A month previously when in his ordinary good health he was wakened in the middle of the night and called out to help at a fire in the village in which he lived. He quickly dressed, went out, and took his place in a line of men which was formed to pass buckets of water up to the scene of the fire. He worked hard at this for several hours, during which he got hot and exhausted in his arms and the upper part of his body, while his feet and legs were wet and chilled by the water which was accidentally spilled on them in rapidly passing on the buckets filled with water. After this he was seized with a severe pain in the lumbar region and the legs felt cold and numb. The pain was relieved by the application of blisters, but the sensation of cold and numbness persisted, being accompanied by a steadily increasing loss of muscular power, so that by the end of a week both legs were completely paralysed. This was shortly followed by some difficulty in micturition with constipation. At the end of a fortnight from the commencement of the illness there was retention of urine with loss of control over the rectum. Since then the regular use of a catheter had been necessary and the fæces had been passed unconsciously. The family history was unimportant and the only previous illnesses from which the patient had suffered were pleurisy and influenza.

On admission into the Infirmary a month after the beginning of his illness the patient lay on his back in bed complaining of a sensation as if a girdle were tied round him midway between the ensiform cartilage and the unbilicus and of pain in the lower part of the abdomen which was increased when the bladder became full. There was complete paralysis of both lower limbs and of the abdominal muscles as high as the umbilicus, combined with loss of all forms of sensation up to the same level. There was no control of the bladder, which if not emptied by means of a catheter filled and then overflowed. The control of the rectum was also lost, the fæces being passed unconsciously into the bed. The motor power of the muscles of the arms and neck and of the trunk above the level of the umbilicus was retained and the sensation of the skin covering these parts was not affected. The plantar and superficial abdominal reflexes up to the level of the umbilicus were absent, but the cremasteric reflex was still present. There was no ankle clonus; the knee-jerks were still present but the response was very slight and feeble. There was a large bed-sore over the sacrum. The urine was acid in reaction, but had a very foul smell and contained both blood and pus. The temperature on admission was 103·4° F.

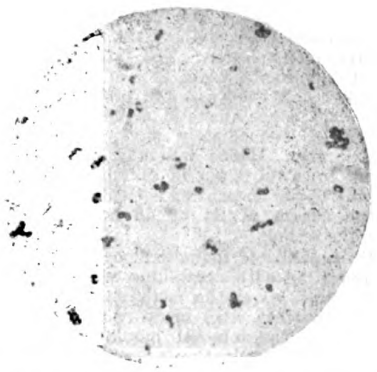
During the first few days that the patient was in the Infirmary the condition remained much as above and the temperature fell to normal (*vide* Fig. 1). On the evening of the 11th there was a severe rigor, the temperature rapidly rising to 105° at 8.30 P.M. On the following morning the temperature was normal again, the pulse was 150, and the respirations were 28. The patient complained of difficulty in breathing and of pain in the lower part of the left side of the chest and at the epigastrium. The upper part of the chest expanded freely, but the expansion of the lower part was deficient. There was general tenderness on pressure all over the abdomen, which was most marked over the kidneys. The knee-jerks were still present and a slight plantar reflex could be obtained on the left side but not on the right. On Jan. 15th the patient began to hiccough and this continued for a week. On some days the hiccough only ceased for one hour out of every three or four and the hypodermic injection of the fifth of a grain of morphia only controlled it for a couple of hours at a time. On the 17th the upper limit of anæsthesia was found to run midway between the umbilicus and the centre of Poupart's ligament, at which level it subsequently remained. The pulse was 82. The abdomen was distended but resonant all over. The left plantar, the cremasteric, and the patellar reflexes could still be obtained, but the response was very feeble. The patient gradually got worse and on Jan. 24th the muscles of both legs were found to be much wasted, soft, and toneless. The plantar reflexes had disappeared and no knee-jerks could be obtained. After this the patient gradually sank and died at 11.30 A.M. on Jan. 27th, seven and a half weeks after the commencement of the illness.

Necropsy.—Unfortunately, no full post-mortem examination was allowed and leave could only be obtained to open the spinal canal and remove the spinal cord. This was done on Jan. 27th at 5.30 P.M., six hours after death. As soon as the spinal canal had been opened some of the lymph which was

FIG. 1.

Temperature chart of a case of meningo-myelitis.

lying on the surface of the dura mater in the upper dorsal region was raised from the dura mater by means of a pair of sterilised forceps, a platinum wire was pushed up between the two, and stroke cultures made on agar-agar and on serum-agar tubes. In this manner inoculations were made direct from the under surface of the layer of lymph, where it lay in contact with the dura mater. The dura mater was then opened with sterilised instruments and stroke cultures on agar were made in the same way from the surface of the pia mater in the mid-dorsal regions. Transverse cuts were then made across the cord with a sterilised knife in the dorsal region on a level with the roots of the fourth and fifth dorsal nerves, and also in the lumbar enlargement. A sterilised platinum loop was then pushed into the substance of the cord itself from the freshly-cut surface in each of these situations, and stroke cultures were made on agar-agar and on serum-agar tubes. After the spinal cord had been removed it was found that there was a communication between the spinal canal and the large bed-sore over the sacrum. This communication may, however, have been accidentally made at the time of the necropsy.



All the tubes were placed in the warm incubator at 37° C. on the same evening. After hardening, sections of the spinal cord from the dorsal region were cut and stained with picro-carmine and then by Weigert's modification of Gram's method. It was found that if the washing with aniline oil was carried on until all the violet colour had disappeared from the substance of the cord and pia mater the micro-organisms were also decolourised, but when the aniline oil was removed while the violet colour was still distinguishable to the naked eye in the pia mater the micro-organisms were well stained. In sections thus prepared large numbers of a small oval bacillus were seen in the pia mater. In some places the bacilli were stained at the extremities and clear in the centre, closely resembling diplococci. The bacilli were lying singly or in irregular chains. One or two longer rod-shaped forms were seen, but with this exception no other forms were found. The oval bacilli were also seen in small groups here and there in the white substance of the cord itself and separated from the pia mater, but the further from the surface of the cord the fewer the groups became.

Cultures.—The tubes were inoculated and placed in the incubator at 37° C., as already mentioned, on the evening of Jan. 27th. No visible growth had appeared on the 28th, but on the morning of the 29th, after the tubes had been about 40 hours in the incubator, colonies had appeared in all the tubes except in one tube of serum-agar inoculated from the substance of the lumbar enlargement. In this tube, however, a growth had also developed by Feb. 1st. Ten tubes in all had been inoculated from the meninges and from the cord itself. In eight of these the growth proved on microscopical examination to be a pure culture of a short oval bacillus. The other two showed similar growths, but in one of them it was mixed with a few larger and longer bacilli, and in the other with some chains of streptococci. As far as naked-eye appearances went the growth in each of the pure cultures had the same appearance. On microscopical examination slight differences in appearance were found in the different cultures. In all the bacillus was short, the length not being more than double the breadth, though there was some difference in the actual size in different specimens. Slight differences were also due to different degrees of staining; in some cases the oval bacilli were stained all through, in others the ends only were stained and the centre clear, so that they resembled diplococci. We consider, however, that they are rightly described as short oval bacilli with polar staining. The appearance is well shown in Figs. 2 and 3, micro-photographs which were kindly taken for us by Mr. H. R. Spitta. Fig. 2 was taken from a film prepared from a pure culture obtained directly from the substance of the spinal cord on a level with the roots of the fourth dorsal nerve. Fig. 3 was taken from a film preparation from a pure culture obtained from a guinea-pig's blood after subcutaneous inoculation with a broth sub-culture obtained from the growth shown in Fig. 2. In the hanging drop the bacillus was seen to be motile. It grew readily at 37° C. on nutrient agar. Isolated colonies on agar at the end of 40 hours in the incubator were small and translucent and resembled minute droplets of condensed moisture. They became rather milky in appearance when older. In a uniform stroke culture a translucent slightly opalescent layer was found at the end of 48 hours. At ordinary temperatures it grew in gelatin which it liquefied.

Inoculations.—The pathogenic properties of the bacillus were tested in a guinea-pig and in a rabbit. For this purpose a tube of nutrient broth was inoculated from the agar

culture obtained from the substance of the spinal cord in the upper dorsal region and incubated at 37°C. for 24 hours. At the end of this time an abundant growth of bacilli had taken place in the broth. One cubic centimetre of this broth culture was injected with the usual antiseptic precautions beneath the skin of the inner side of the thigh of a brown male rabbit, and a similar quantity of the same culture was also injected into a red-and-white male guinea-pig in the same situation. On the following day the guinea-pig looked ill, the temperature in the morning being 100·6°F., and in the evening 99·4°. On the next morning it was found dead in

FIG. 2.

Film preparation of culture obtained from substance of spinal cord.

the cage. No naked-eye changes were found at the post mortem examination. Films were prepared from the blood from the heart and stained. Agar tubes were inoculated from the blood in the heart, and films were prepared from the cultures which developed. On microscopical examination of the blood a few widely-scattered micro-organisms which resembled diplococci without any capsule were found. In the hot incubator a pure culture of the original bacillus developed on agar, so that the micro-organisms in the blood were really bacilli with polar staining and not diplococci, the actual form being more easily seen in pure cultures than in the blood itself.

FIG. 3.

Film preparation of culture obtained from blood of guinea-pig after inoculation.

Fig. 3 shows the specimen prepared from the agar culture obtained from the blood of the guinea-pig. In the case of the rabbit, on the day after the inoculation the temperature in the morning was 102° and in the evening 104°. The animal was very quiet and the respiration was rapid and laboured. The following morning the temperature had fallen to 100·2° and a swelling had formed at the seat of the inoculation. After this the temperature only varied between 100° and 101°. On the fourth day after the inoculation the right side of the scrotum was swollen and the rabbit was killed. The right tunica vaginalis was distended with thin serous fluid and the right testicle was swollen. A slough had formed at the seat of inoculation. Tubes were inoculated from the heart blood and from the tunica vaginalis. No colonies developed from the blood but an abundant pure growth of the original bacillus developed in the tube inoculated from the tunica vaginalis. In the guinea-pig, therefore, the subcutaneous inoculation of a pure culture of the bacilli produced a rapidly fatal general infection without local reaction, whereas in the rabbit there was no general infection, but a local reaction, with sharp rise of temperature, limited to the neighbourhood of the inoculation. No nervous symptoms were observed in either of the animals.

The characters of the micro-organisms may be shortly summarised as follows. A short oval motile bacillus which stains readily by aniline dyes, the stain in many cases showing a much stronger affinity for the ends than for the centre of the bacillus. It can with care be stained by Gram's method and was found in large numbers in the pia mater and also in lesser numbers in the substance of the cord. Pure cultures of the bacillus were obtained both from the meninges and also from the substance of the cord itself. Subcutaneous inoculation caused rapid general infection in the guinea-pig and a local infection in the rabbit. The bacillus grows readily on the ordinary nutrient media in both the hot and cool incubators. It liquefies gelatin.

In this case we have a clear history of an acute onset of the meningo-myelitis following an exposure to cold and wet combined with fatigue. The similarity to the sequence of events often observed in the development of an attack of acute lobar pneumonia is striking, so that it seems very probable that the myelitis, like a pneumonia, was the result of an infection occurring as a result of a temporary lowering of resistance. This view is strongly supported by the presence of a micro-organism in the meninges and spinal cord, which we have shown was undoubtedly possessed of pathogenic properties.

Micro-organisms have been found and cultivated in several cases of acute meningo-myelitis, notably in the case so well recorded by Dr. T. Buzzard and Dr. Risien Russell.[1] They obtained a culture of a diplococcus in one tube which was inoculated from the meninges in the lumbar region, the other tubes showing no growth. The organisms seem to have been less numerous than in our case, as growth developed in all the tubes we inoculated. Similar diplococci were seen in stained sections in the exudation, in the meninges, and in the substance of the cord, just as in our case. The organism in our case differs from that found by Buzzard and Russell in that it more nearly resembled a bacillus with polar staining than a diplococcus—a difference that is perhaps more apparent than real—it liquefies gelatin, and can be stained in sections by Gram's method. It differs from Weichselbaum's diplococcus intracellularis in appearance and, unlike it, grows in the cool incubator and does not appear within the cells of the exudate.

In Dr. E. F. Trevelyan's case[2] a diplococcus was obtained from the pus outside the dura mater and also from a softened patch in the cord; the bacteriological examination was, however, not carried further as the micro-organisms died in a few days.

The value of the bacteriological examination in our case is, of course, much diminished by the fact that the bed-sore was in such close proximity to, if not in actual communication with, the spinal canal, but we consider that if the infection of the cord had been secondary to the foul bed-sore the cultures would have been mixed and not pure in all except two tubes, as was the case. The evidence we at present possess goes a long way to show that acute meningo-myelitis is probably an infective disease, and although it cannot as yet be attributed to any single organism the bacteria which have been found in the recorded cases appear to have certain characters in common.

Newcastle.

LOCAL SANITARY AUTHORITIES AND THE MILK-SUPPLY.—The bacteriological examinations conducted by the St. Pancras Vestry have proved that out of 50 samples only 16 were normal, five contained tubercle bacilli, and the remainder from various causes were not fit for human consumption.

A BLOOD REACTION IN DIABETES MELLITUS; ITS CAUSE AND DIAGNOSTIC VALUE.

BY R. T. WILLIAMSON, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE ANCOATS HOSPITAL, MANCHESTER, AND ASSISTANT LECTURER ON MEDICINE AT OWENS COLLEGE.

IN 1896 I recorded[1] a reaction which I believe to be peculiar to the blood of patients suffering from diabetes mellitus. A drop of blood taken from the finger of a diabetic patient decolourises a warm alkaline solution of methylene blue, when mixed in certain proportions, whilst blood from healthy persons or from individuals suffering from other diseases has no such action when mixed in the same proportion. The reaction is due to the greater reducing power of diabetic blood and is obtained as follows. At the bottom of a small, narrow test-tube is placed a drop of water—40 cubic millimetres. To this are added 20 cubic millimetres of blood taken from the finger of the diabetic patient. Then 1000 cubic millimetres (one cubic centimetre) of a watery solution of methylene blue (1 in 6000), and finally 40 cubic millimetres of liquor potassæ (B. P.) are added. Into a similar tube are placed 20 cubic millimetres of normal blood with the same proportions of methylene blue and liquor potassæ. The mixed fluids in each tube will have a fairly deep blue or bluish-green colour. Both small test-tubes are placed in a beaker or very large wide test-tube containing water and the water is heated and kept boiling for four minutes. At the end of this time the fluid in the small test-tube containing the diabetic blood will have lost its blue colour and become dirty yellow, whilst that in the tube containing non-diabetic blood will remain blue or bluish-green. (The exact quantities of the fluid used may be measured by the small tubes supplied with the hæmocytometer and hæmoglobinometer of Gowers.)

I have examined the blood in 43 cases of diabetes mellitus and have always obtained the reaction mentioned. I have examined the blood in 100 cases of other diseases of the most varied forms and also the blood of healthy persons on innumerable occasions, but, when the fluids have been mixed in the proportion above stated, have never obtained the reaction. My results have been confirmed in Germany by Loewy,[2] Goldscheider,[3] and R. Müller[4]; in France by Le Goff,[5] P. Marie, Lyonnet,[6] and Lépine; in Italy by Baduel and Castellani,[7] Ferrannini,[8] and Lucibelli[9]; and in America by Futscher[10] (in Professor Osler's clinic). Further observations which I have made indicate the cause and diagnostic value of the reaction.

CAUSE OF THE REACTION.

1. This reaction, peculiar to diabetic blood, is evidently due to the presence of some substance in solution in the blood serum. Large quantities of blood obtained post mortem from the internal jugular vein of three cases of diabetes mellitus were allowed to stand until the serum separated on the surface and the red corpuscles sank to the bottom of the vessel. In each case the blood serum, free from red corpuscles, gave the reaction—i.e., decolourised methylene blue in the proportion given above—whilst the serum obtained in a similar manner from non-diabetic blood gave no reaction (in the proportions mentioned).

2. Blood serum from a diabetic subject loses the power of giving the reaction after it is submitted to the action of yeast. In three cases of diabetes mellitus large quantities of blood were taken post mortem from the internal jugular vein and allowed to stand for 24 hours until the serum had separated. In each case two test-tubes of the usual size were half filled with the diabetic blood serum. To one test-tube ordinary German yeast was added, to the other no yeast was added. Both were kept in a warm place, side by side, for 48 hours, the mouth of each tube being plugged by cotton-wool. At the end of 48 hours the serum in the test-tube containing the yeast gave no reaction with methylene blue (according to the method above described), whilst 20 cubic millimetres of the serum in the tube which contained no yeast gave the reaction readily. The same results were obtained by the blood serum in all of the three cases of diabetes. The diabetic serum which had been submitted to the action of yeast and which did not decolourise methylene blue gave no reaction for sugar with Fehling's solution; whilst the diabetic serum to which no yeast had been added and which continued to give the reaction with methylene blue above described, gave a slight but distinct reaction for sugar with Fehling's solution. The failure of the diabetic serum, after the action of yeast, to give the methylene-blue reaction was not due simply to the presence of the yeast-cells in the fluid, since diabetic serum when mixed with yeast and tested immediately gave the methylene-blue reaction distinctly. Hence we may conclude that the diabetic serum loses its power of giving the methylene-blue reaction, owing to the fermenting action of the yeast fungus, which in the course of 24 or 48 hours destroys some substance in the serum.

3. After the proteids of diabetic blood or serum have been separated, by boiling with crystalline sulphate of soda and filtering, the filtrate gives the methylene-blue reaction. A number of observations were made on the blood obtained post mortem from the internal jugular vein in a case of diabetes. In each examination an ounce or more of the blood or serum was mixed with an equal quantity of crystalline sulphate of soda and the mixture was boiled until the froth above the clot became white and all red specks disappeared. In every examination 20 cubic millimetres of the clear filtrate gave the methylene-blue reaction above described. When non-diabetic blood was treated with sodium sulphate in the same way the filtrate failed to give the methylene-blue reaction.

4. After the separation of the proteids of diabetic blood the power of giving the methylene-blue reaction is destroyed by the action of yeast. In another experiment, two test-tubes were half filled with the clear filtrate, obtained after separating the proteids of diabetic blood by boiling with sodium sulphate, as just described. To the fluid in one test-tube a little German yeast was added, while to that in the other tube no yeast was added. The mouth of each tube was plugged with cotton-wool and the tubes were kept in a warm place for 48 hours. Then the fluid in each tube was examined for the methylene-blue reaction above described. 20 cubic millimetres of the fluid from the test-tube of filtrate to which yeast had been added gave no reaction; 20 cubic millimetres of the fluid from the test-tube to which no yeast had been added gave the reaction markedly. The fluid in the test-tube to which yeast had been added gave no reaction for sugar either with Fehling's solution or phenyl-hydrazin, whilst the fluid in the other test-tube, to which no yeast had been added, gave a reaction for sugar both with Fehling's solution and phenyl-hydrazin.

5. It is well known that glucose has the power of reducing a warm alkaline solution of methylene blue. 20 cubic millimetres of a watery solution of glucose (5 in 1000) gave a distinct reaction with the methylene-blue test; but 20 cubic millimetres of a 2·5 in 1000 solution did not. When 20 cubic millimetres of the 2·5 in 1000 solution of glucose were added to 20 cubic millimetres of normal blood, the mixture decolourised the alkaline methylene blue like diabetic blood, but 20 cubic millimetres of the blood alone, or of the 2·5 in 1000 glucose solution alone, failed to give the methylene-blue reaction.

6. Though non-diabetic blood does not give the methylene-blue reaction in the proportions stated at the commencement of this article, it has nevertheless some reducing action in larger quantities. In performing the methylene-blue blood test it is always necessary to measure accurately the quantity of blood employed (20 cubic millimetres), since the diabetic reaction depends on the greater reducing power of the diabetic blood. As already stated, I have never obtained the reaction when 20 cubic millimetres of blood were employed, in any condition except diabetes mellitus. But with normal blood a reaction may be obtained when 60 cubic millimetres of blood are employed in performing the test; also

60 cubic millimetres of normal blood serum decolourise the methylene-blue solution. (20 cubic millimetres of serum have no action, just as in the case of 20 cubic millimetres of blood.) Hence there is also some substance in normal blood that has a reducing action when a sufficient quantity of blood is employed. This substance is in solution in the serum. But it is not simply the minute quantity of glucose, of normal or non-diabetic blood, since this reducing power is not destroyed by the action of yeast. Thus, two test-tubes of ordinary size were half filled with blood obtained post mortem from a case of aneurysm. To one test-tube yeast was added; to the other no yeast was added. Both were kept in a warm place for 48 hours. At the end of that time 60 cubic millimetres of blood from *each* tube reduced the methylene-blue solution readily. Hence there is a substance in non-diabetic blood, beside the minute quantity of sugar, which has some slight reducing action on methylene blue.

7. It is interesting to note that 20 cubic millimetres of diabetic urine gave the methylene-blue reaction markedly, whilst 20 cubic millimetres of the same diabetic urine in which the sugar had been decomposed by the action of yeast no longer gave the methylene-blue reaction; also 20 cubic millimetres of normal urine did not give the methylene-blue reaction.

Briefly summarised the results of the observations recorded may be stated as follows. The methylene-blue reaction, carried out with the proportions of fluid stated at the commencement of this article, may be obtained with a solution of glucose; it is obtained with diabetic urine, with diabetic blood, with diabetic blood serum, and with the filtrate from diabetic blood when the proteids have been separated by boiling with crystalline sodium sulphate. All of these fluids after the action of yeast fail to give the reaction. As already mentioned, when a dilute solution of glucose is added to normal blood the methylene-blue reaction is obtained. All these facts indicate that the methylene-blue reaction given by diabetic blood is due to the excess of glucose which it contains.

CLINICAL AND PATHOLOGICAL VALUE OF THE REACTION.

The methylene-blue reaction of diabetic blood is exceedingly delicate and may be obtained even when the urine contains only a very small quantity of sugar. Usually there is no difficulty, however, in diagnosing diabetes mellitus clinically. The examination of the urine is generally sufficient. The methylene-blue reaction of the blood is present in diabetic coma, and in this condition if the urine could not be obtained for examination (i.e., if the bladder should be empty) the blood reaction would be diagnostic. R. Müller[11] has recorded a case of diabetic coma in which the diagnosis was definitely made by the blood reaction which I have described, the bladder being empty and no urine being obtainable.

In the post-mortem appearances of persons dying from diabetes there is nothing characteristic. In the case of an individual dying from diabetic coma, if no history of the diabetic symptoms before the onset of coma could be obtained and if no urine could be found in the bladder nor any obtained which had been passed before death, a pathologist would not be able to diagnose the disease from the post-mortem appearances. Such cases, no doubt, have sometimes remained unrecognised in the past, and probably some of the obscure cases in which post-mortem examination made for the coroner has failed to reveal a satisfactory cause of death have been due to diabetic coma. The methylene-blue blood reaction in such cases would be diagnostic.

In five cases of diabetes mellitus I have removed blood from the internal jugular vein post mortem, and in every case 20 cubic millimetres of the blood gave the methylene-blue reaction markedly. Further, it is an interesting practical point that the reaction is obtained many hours after death. Thus in a case of diabetic coma in which the post-mortem examination was made 16 hours after death three ounces of the blood were placed in a bottle. Three days later the methylene-blue reaction was obtained markedly. In another case, blood removed from the internal jugular vein 10 hours after death gave the methylene-blue reaction after it had been kept in a bottle for a week. The reaction, of course, is obtained early as well as later. I obtained it in one case in the blood taken from the internal jugular vein three hours after death. I have examined the blood taken post mortem from the internal jugular vein of 20 individuals dying from various other diseases but have never obtained the reaction.

Hence this reaction may be of practical diagnostic value, pathologically and medico-legally, in certain cases. I think it is advisable, when the blood is examined post mortem, to always take it from the internal jugular vein. Blood from this vein is not liable to be contaminated by other fluids during the necropsy. It is possible, also, that this delicate reaction may be made the basis of an easy method of estimating the amount of sugar in the blood. Two methods have already been worked out by Lyonnet and Le Goff, but it remains for future observations to show whether these methods are more delicate and reliable than those commonly employed.

THE ETIOLOGY OF SCURVY.

BY W. E. HOME, B.SC., M.D. EDIN.,
STAFF SURGEON, R.N.

I SHOULD like to offer some remarks on the very interesting paper of Mr. F. G. Jackson and Dr. V. Harley on Scurvy which appeared in THE LANCET of April 28th and to submit a suggestion as to the etiology of this important disease which has become so rare that I cannot be quite certain that I have ever seen a case. The orthodox view is that it occurs in people who live on a diet deprived of green vegetables or potatoes, its onset being accelerated by preceding hardships, while it is prevented by a daily ration of lime-juice and cured by lime-juice or fresh vegetables. Torup and Nansen suggested that it might arise from ptomaine posioning, which was noted in THE LANCET of Feb. 13th, 1897, as a new departure, and this suggestion Mr. Jackson and Dr. Harley endeavour to support by their research reported in THE LANCET of April 28th. They fed six monkeys on sound meat and 13 on tainted meat and in these last found evidences of scurvy—namely, as they say, bloody mucus in the stools, spongy gums, and characteristic anæmia; also there were post-mortem appearances of irritation in the mouth (spongy gums—that is to say, I suppose, inflammation of the gums—going on to ulceration) and irritation of the large intestine. They consider their observations support the theory that "scurvy is essentially due to poisoning by the ptomaines of tainted animal food." In their experiments, however, they did not take care to administer ptomaines only, but as the "sour-smelling meat" on which the second lot of monkeys were fed had not been sterilised, only as they say "gently heated," the monkeys got not only ptomaines but also the living bacteria which produced the ptomaines. What is there, then, in these experiments to prevent us from believing that the bacteria of putrefaction were taken alive into the mouths of the monkeys, there infecting the sordes round the teeth and setting up gingivitis, going on to ulceration, infecting also the gastro-intestinal canal later, these parasitic infections setting up the anæmia on which all the other symptoms of scurvy depend? Anæmia is generally the effect of the struggle of the organism against some infection. How pale a person becomes after suffering for a couple of days from a large boil, and think of Hunter's most valuable researches into the etiology of pernicious anæmia and Sir Andrew Clark's explanation of chlorosis. Clearly the anæmia will develop all the faster if the victims are, as so often happens in epidemics of scurvy, on short rations, particularly if they are taking in fresh doses of the poison with each scanty meal, and they probably were taking in fresh doses with each mouthful, for Lind describes their beef as rotten, their pork as rancid, their flour as mouldy, and their water as unwholesome. And Gillespie describes the beef the men had to eat in the Persian Gulf as so rotten that it could not properly be boiled. They tied it up with strings but it fell out of them, wherefore their Arab pilot greatly pitied them and preferred rather to go ashore where there was a great epidemic of plague than to remain in their ship where he could get no other food.

It is curious that in the same number of THE LANCET (April 28th) there should be an account of a case of pernicious anæmia associated with, and in the opinion of Dr. W. Elder mainly due to, neglected state of the teeth, cured by buccal antisepsis, anti-streptococcic serum (the

most evidently beneficial treatment), and salicylate of bismuth. We have all heard stories of leading consulting physicians who have refused to advise patients suffering from dyspepsia till their teeth were put in order. Have we not now a scientific reason for this seemingly arbitrary action by the practical man?

I am greatly interested to have this suggestion that the initial lesion of scurvy is an affection of the gums; it harmonises much of the contradiction which exists in the historical pathology of this disease. I would submit as a nearer approximation than we have yet had to the true etiology that scurvy is caused by micro-organisms "as yet unknown" which infect the alimentary canal, setting up primarily a gingivitis and later an anæmia which leads to hæmorrhages and predisposes to ulcerations, more frequently threatened as these last were in ships where long cruises with their scarcity of provisions and of water made cleanliness much more difficult. These micro-organisms may be destroyed by antiseptics. (Osler recommends permanganate of potash and dilute carbolic acid for the stomatitis and solution of nitrate of silver for the ulceration of the gums.) Lime-juice cures scurvy either specifically (as quinine antagonises the malarial organism or as mercury resists syphilis) or it may act as an antiseptic which can be taken into the mouth and swallowed strong enough to do the mouth good and destroy the parasite without doing the rest of the body harm. That it is useful I suppose no one will deny, but as many people have forgotten why we think so I may narrate Dr. Galleraud's experiences. In the *Psyché*, in the White Sea, in 1854, he had a severe epidemic which only ceased when the vessel returned to France. Next year in the *Cléopâtre* he was threatened with a more serious epidemic, but Dr. Murray of the *Meander* told him about our lime-juice and got for him 11 gallons from the *Meander* and *Phœnix*, by the help of which he put a stop to the epidemic in the *Cléopâtre*, and the French Admiralty was so convinced by his experiences of the usefulness of lime-juice that they made it a general issue to their fleet.

But why should lime-juice be so beneficial? It is not only an acid but also contains aromatic principles, and each of these classes of substances has been used to cure scurvy. Cook (1772) preserved his crew with sauerkraut; Lind (1779) besides lime-juice recommended vinegar; Blane (1785) (like Lind, an M.D. of Edinburgh) mentions sowens as anti-scorbutic. (There was scurvy in Ladysmith; was there any or as much in Mafeking?) So much for the acids. As to aromatics, the anti-scorbutic plants mentioned are generally cruciferæ. Lind recommends the surgeon to grow mustard and cress on blankets and to give a daily ration of these plants. Cochleariæ are often mentioned; they include not only the various scurvy grasses, as they were called of old, but the nowadays better-known horseradish, and, as we have seen, Osler recommends antiseptics for the treatment of the gums. It may well be that both classes are required. I find that ulcers heal up more quickly when one is not too devoted to a single antiseptic, however potent; most ulcerations result from a mixed infection or symbiosis and are best cured by different antiseptics used alternately, and lime-juice may be the best anti-scorbutic because of its double nature and varied antiseptic effect. Employed as a mouthwash at bedtime it certainly is useful—I suppose as an antiseptic in the prevention of the buccal catarrh commonly ascribed to over-smoking, and very apt to follow late and prolonged dinner-parties. Easton's syrup diluted I have found more effectual, but it is more difficult to insure that your patient shall use it.

In relation to the antiseptic effect of the oils of the cruciferæ I may say that in a small prison in which I once worked we recognised, we thought, an epidemic gastro-intestinal catarrh in the treatment of which we were using up all our peppermint and bitter stomachics until the prisoners got mustard added as a condiment to their daily allowance of three-quarters of a pound of cooked beef, when the fermentative dyspepsia was, as we had expected, checked without drugs. The dyspepsia-causing germ, which thrives best in beef-chyme, grows strongly in the stomachs of people who eat no meat but beef; to depress it we have learnt by experience to take mustard or to vary our diet. I suppose that the germ that thrives best in mutton-chyme is less well antagonised by mustard and that therefore it is we do not eat mustard with mutton. So the old gibe: "Mustard with mutton! Naval officer, I presume," dates back to a day when naval officers, always at sea blockading and living on beef and pork, had not enough experience of mutton to know that mustard was not its appropriate antiseptic condiment. I suppose, too, that the principle of the varying of diet which I mentioned above explains why children, dyspeptic while living exclusively on milk, are often cured by raw meat juice. The infecting organism, which probably entered the stomach with milk and has been living in milk-chyme, finds the environment less favourable when raw meat juice replaces milk, is weakened and now more easily destroyed by the remedies formerly powerless against it.

Since I have read William Hunter's papers on pernicious anæmia I have realised more clearly than even before how important a factor in the causation of tropical anæmia and debility is the infection of our alimentary canals by the saprophytes which so plentifully surround us in those regions of luxuriant vegetation. From these infections the natives strive to save themselves by eating curries and chewing peppers and other "hot things"—that is, aromatic antiseptics. The diarrhœa of Hong-Kong is a proverb—a tradition I myself believe of the time before 1888, when the gravitation supply of upland surface-water was brought in. Still, there is a good deal of diarrhœa which is best treated antiseptically with carbolic acid on Colonel Quill's plan, or with boric acid for the stomach, salol for the small intestine, and enemata of copper sulphate or boric acid for the colon and rectum. It is also worthy of note that many of the Eastern races of greatest vitality, as the Chinese and the Indian, are, as I have seen them, most careful about the morning cleaning of their teeth; the Chinese in addition scrape their tongues with a "strigil," generally attached to the tooth-brush by a chain. The Indians at Zanzibar sit at their doors in the early morning and chew tooth-sticks, with which they poke and rub out all the sordes. In their slow, methodical, and thorough operations they greatly remind me of a former shipmate, the most minutely clean person I have ever known, who used always after breakfast to sit himself down in his cabin for five minutes with a strong toothpick, allowing nothing at this important period to distract his attention from an essential duty. He was certainly more healthy than were most of us.

The only well-known fact about scurvy which I am quite unable to explain by the theory of primary infection of the gums cured by antisepsis is the value of the potato as an anti-scorbutic. Raw or cooked it seems almost as efficient as lime-juice, yet it is not, so far as I know, an antiseptic.

In conclusion, I may recapitulate and say that I suggest that scurvy is essentially an infection of the mouth with micro-organisms out of decayed food, antagonised by lime-juice and fresh vegetables which act as antiseptics, this infection of the mouth being most apt to occur in times of hardship when cleanliness is least within our reach.

H.M.S. *Minotaur*, Portland.

ON THE LIMITATION OF PHYSICAL METHODS IN THE INVESTIGATION OF THE PHYSIOLOGICAL AND PSYCHICAL PHENOMENA OF SIGHT.

BY F. W. EDRIDGE-GREEN, M.D. DURH., F.R.C.S. ENG.

IN a paper published in THE LANCET of May 26th (p. 1511) I showed how difficult it was to correctly ascertain the colour perception of any person if we ignored colour names. In this paper I wish to show that in investigating physiological, psychical, and pathological phenomena we must employ methods which are suited to the case in hand and not those which are so admirably adapted to the study of the physical phenomena themselves. We talk of light and heat as if they were two different things, but the difference exists in us, not in the physical stimuli giving rise to the sensation. The physical stimulus is that force which, acting upon the body, gives rise to a sensation. For instance, the force which, acting upon the eye, gives rise to the sensation of light when falling upon the back of the hand gives rise to the sensation of heat, and may when falling upon the back of the head covered by hair give rise to no sensation whatever. Again, different physical stimuli

may cause the same sensation as a blow on the eye causing the sensation of light. Many years ago a well-known physicist who was discussing my views on colour-vision remarked: "I explain the Young-Helmholtz theory in the following way to show how by the admixture of three constituents we can form all colours. If we take whisky, sugar, and water we can by mixing them in varying proportions obtain mixtures of an unlimited number, each differing from the other." But he was entirely overlooking the man who had to taste the whisky. The mixtures which could be made are innumerable, but the number of distinct mixtures which could be recognised by any person are very limited. In the case of a man who has been accustomed to take a glass of whisky every day for 20 years it is improbable that the constituents were twice alike, viewed from a physical standpoint, but to him they have appeared exactly alike. If my view be correct, that colour is a point of difference perceived by a perceptive centre in the brain, a method which aims at ascertaining the colour perception of an individual by measuring the apparent luminosity of the colours he perceives is as likely to achieve the desired result as it would be if applied to ascertain any other idea of the mind.

I will now give an example showing how inefficient these physical methods are to elucidate the phenomena of colour perception. I was the first to point out that intermediate between normal and dichromic colour vision there are those whose vision is pentachromic, tetrachromic, and trichromic. Let us consider those whom I have designated as having trichromic vision, because it has been asserted by so many physicists that normal colour vision is trichromic. A person whose colour vision is trichromic may see a spectrum of the same length as the normal-sighted, but he sees only three colours—red, green, and violet. He sees no orange, yellow, or blue in the spectrum. In fact, many have remarked to me that red-green would be a far better name than yellow and violet-green than blue, and they frequently used these terms. Yellow and orange do not appear to them as definite colours, but as transition colours between red and green. Tested in every possible way it is found that their vision is trichromic; they never mistake red and green for each other and laugh at the possibility of making this mistake, but are always in difficulty over orange, yellow, and blue. In a classification of colours the same mistakes are made: some yellows are put with red, others with green; some blues are put with violet, others with green. Yet examined by physical methods these persons may appear normal-sighted, and I may mention that several colour-blind persons of this class have been passed by a physicist as normal-sighted. It is obvious that a method of colour-matching which has for its theory that normal vision is trichromic will show that these persons are normal-sighted. They usually pass the Holmgren test with ease. They are, however, most dangerous persons at sea, as they are never certain about a yellow light and continually confuse it with red and green. When I was appointed by the Board of Trade to advise that body on the subject of colour-blindness one of the first cases that was referred to me was of this kind. The man could always distinguish between red and green, but was continually in doubt about yellow. It must be perfectly obvious to the reader that a man who cannot see any yellow in the spectrum and who thinks that red-green would be a better name for yellow cannot have normal colour vision. To me, the yellow of the spectrum or a yellow flower appears an absolutely distinct colour, in which it is not possible to distinguish either red or green. Blue and orange are also absolutely distinct colours to me.

I will now give a bare outline of my views on the perception of colour[1] as it will make the points which I wish to discuss more intelligible. I believe that light acting upon the retina liberates the visual purple from the rods and a photograph is formed, the cones and optic nerve-fibres conveying the impression to the brain. Kühne stated that the visual purple cannot be essential to vision as it is absent from the cones and only cones are to be found in the fovea centralis, the region of most distinct vision. This fact, however, furnished me with a ready means of testing the truth of my theory. I have made numerous experiments which prove that unless light falls as well on a portion of the retina containing rods it may fall on the fovea centralis without producing any sensation. The reader may convince himself of this by a very simple experiment. Fasten a piece of black velvet about three feet square on a door, and in the centre of the velvet put a pin so that the head is directed towards the observer. If the source of light be behind the observer the pin will be brightly illuminated, but on looking at it and keeping the eyes quite still the pin will disappear, the visual substance diffused into the fovea centralis being used up and not renewed. When viewed by indirect vision it is impossible to make it disappear in this way. Single isolated stars when not too bright may be made to disappear in a similar manner. In a dim light and with one eye shut a large portion, and sometimes the whole, of the field of vision will become totally black from the centre outwards. In this experiment the whole of the visual substance is used up and not re-secreted. It is easy to suppose that the visual substance becomes liquefied and diffused into the fovea centralis. This theory is supported by some hundreds of experiments, for instance that the area of greatest luminosity of the retina is at the point where the rods are most abundant, &c. This view occurred to me when I had not one-twentieth part of the evidence in favour of it which I have now. But during the last 10 years I have collected evidence that proves not only that there is a visual substance but that that substance is purple—namely, the complementary of pure green. It is probably only seen as purple when in excess. Under certain conditions a purple after-image can be obtained after white light and every spectral colour. If we rub one of our eyes in a dark room a purple light appears. It will be noticed that the visual purple is in every way suitable for the visual substance. It gives a continuous spectrum. It is easy to suppose that light might liberate the visual substance just as heat melts an ointment, but we have evidence that the cones themselves help. Engelmann and Van Genderen Stort have shown that there is a shortening of the inner segments of the cones under light, but this cannot convey any light sensation, as the same action has been found to take place when the light falls on another part of the body. This action would cause a vacuum. In my experiments, in which I have caused lights to apparently disappear, I find that the experiment succeeds best if only one eye be used and the greatest care be taken that no light falls on the face or any other part of the body. I believe that shortening of the spectrum is due to some defect in this visual substance as there is light as well as colour loss, which is not the case with colour-blindness due to defective psycho-physical perception. The visual substance being decomposed by light sets up by chemical, mechanical, electrical, or some other physical action, impulses which are conveyed to the brain through the cones and optic nerve-fibres, the cones being the terminations of the perceptive fibres in the retina. The whole impression being brought to the centre of memory, different portions of the impression—colour, form, size, luminosity, &c.—are conveyed to the mind through definite perceptive centres. In the case of colour, this perceptive centre is only able to distinguish six definite points of difference (colours) in the spectrum which really presents millions. We, therefore, for the normal-sighted have a hexachromic theory of colour-vision which is independent of light and shade. A hexachromic theory will obviously explain all that can be explained by a trichromic theory. It also agrees with the fact that both blue and violet have been demonstrated to be primary. I may say that I totally disagree with the theory that normal colour vision is trichromic, and am of opinion that the curves and equations which have been constructed to prove that vision is trichromic are mathematically incorrect. I have raised this point as an objection to the Young-Helmholtz theory in a paper recently read before the Royal Society. Equal stimulation of the three sets of fibres is supposed to cause the sensation of white light. Red and green when mixed make yellow. Violet and green when mixed make blue. But yellow and blue when mixed make white, which makes one portion of green too many, thus:—$R + G = Y$, and $G + V = B$, but $Y + B$ = white, therefore, $R + G + G + V$ should equal white, but $R + G + V$ = white.

The degrees and varieties of colour-blindness are perfectly explained by the theory of psycho-physical perception. Assuming that the perceptive centre is smaller fewer points of difference are seen. The phenomena of contrasts are explained on the view that colour being a point of difference this becomes more marked on comparison. If we contrast a yellow with a greenish-yellow the yellow inclines to orange

[1] Colour Blindness and Colour Perception, International Scientific Series.

and the greenish-yellow to yellow-green. This could not be explained by assuming that the colours differ by the addition of the complementary to each, as the complementary of yellow is blue and this mixed with yellow would make white instead of orange-yellow.

In addition to the points which I have already raised the following appear to me as serious objections against the ordinary physical methods of ascertaining the colour perception of an individual.

Absorption of light by the media of the eye.—It is obvious that the media of the eye vary slightly in colour in different persons. This produces a variation of the colour curve in each case without in any way affecting the real colour perception of an individual. For instance, a normal-sighted person's vision is still hexachromic when he looks through a pale yellow glass.

Hyperæsthesia to certain colours.—Another source of error in matching colours with white light is that persons differ as to their sensibility to all colours or to certain of them just as they differ in their physiological actions in other parts of the body. One person can read in a very feeble light but is dazzled by a light which to another person is quite comfortable. A person of this kind matches a red with a grey which is much darker than that chosen by another person, though both may have equally good colour perception. Again, men vary as to their sensibility to certain colours; one is more affected by red, another by green, and another by yellow. We can also have temporary hyperæsthesia, an exaggerated example of which is found in photophobia.

Idea as to comparative luminosity.—In matching colours with white light or with each other much depends upon the observer's idea of the colour. If I make a match of red and grey with the idea that red is a very bright colour I shall make a match with a much lighter grey than I should if I had the idea that red was a very dark colour.

If the theory as to a photo-chemical substance be admitted then the action of light on the substance may produce an excessive reaction with one person and very little with another; the apparent luminosity would be much greater in the first case. The secretion of fresh photo-chemical substance may be quicker in one person than in another. We know that the visual purple may be bleached by monochromatic as well as by mixed light. If we suppose the visual substance of the eye to be decomposed in the same manner it would be possible to understand that we might get similar curves of luminosity by different colours though the visual impulses sent to the brain might in each case be different. If there be, and all recent research points to the fact that there are, different centres in the brain for the perception of luminosity and colour, it is obvious that ascertaining the luminosity of a colour will not give us any information concerning that colour because the two are absolutely and totally distinct. In order to make my meaning clearer I will make a comparison with the organ of hearing. The perception of pitch is in every respect analogous to the perception of colour and yet no one would dream of endeavouring to obtain any information concerning the pitch of a note by observations on the intensity with which it is struck.

In conclusion, I will point out that we must always be careful in examining a person by physical methods that we do not obtain results which are only physical, chemical, and electrical phenomena. When the phenomena are psychical they can not be measured by the balance and the rule but must be gained by direct evidence from the mind itself.

Hendon.

SOME REMARKS UPON THE TECHNIQUE OF OPERATIONS DESIGNED TO CURE RADICALLY OBLIQUE INGUINAL HERNIA.

BY FREDERICK D. BIRD, M.S.,
LECTURER ON SURGERY AT MELBOURNE UNIVERSITY.

THE introduction of Bassini's method of operating for the radical cure of inguinal hernia, whatever opinion we may have of its efficiency, undoubtedly gave a great impetus to the study of the subject. Several modifications in the direction of further elaboration soon appeared, and some of these—notably, the diminishing of the size of the spermatic cord by removal of an excess of veins—are of undoubted utility in certain cases. Whilst a strong adherent of Bassini's procedure, it has always struck me as unsurgical to follow all its details in every case. Our object in attempting a radical cure of hernia is to attain a certain security and not to perform any particular method of operating, no matter how good that may be. We desire to obtain future immunity against hernial protrusion by means as simple as possible, by means which damage and disturb the tissues as little as possible, and by means which leave the part as nearly as possible in the condition which obtains when there is no hernia.

The operation for radical cure of an inguinal hernia must be looked upon as essentially an abdominal incision. The main principles which guide and restrain our technique in opening the abdomen must be allowed full weight in our hernial operations. Thus the smallest incision which allows our free working is the best; a good inch or more of the skin incision, generally made on towards the pubes, is, as a rule, unnecessary. I often find now that it is not requisite to incise the skin internally as far even as the external ring. The tissue in this region carries a good deal of fat, much more than further out, and it is easily split into planes, which fact allows of ready infiltration of blood, and as it is furnished with one or two fair-sized arteries and two or more fair-sized veins the leaving of it intact is a matter of some importance in the saving of time and keeping the operation area dry from blood. If the incision through the skin and subcutaneous tissue is made well above the level of Poupart's ligament a region is entered which allows of marked mobility, so that if the operator wants it he can lift the skin and subcutaneous fat with the vessels in one piece on the forefinger and thus expose the external ring. On the other hand, I extend the skin incision well beyond the site of the internal ring.

From an incisional point of view Poupart's ligament in the operation partakes largely of the nature of a bony margin, therefore the further away from it we can keep the better for the future integrity of our scar. Thus the best skin incision, in my opinion, is one which is a full inch above Poupart's ligament and which does not invade more than slightly the pubic thickening of subcutaneous fat and which ends internally, of course, far from the commencement of the scrotum. Our objective, no matter how large the hernia, is, in the operation for the radical cure, as in the operation for the relief of strangulation, the point of exit of the hernia from the abdomen, and this in inguinal hernia is, in the vast majority of cases, the internal ring. Again a well-healed scar on the abdomen is of no moment, whilst the scar intruding on the flexure of the groin may be inconvenient. The deep layer of the superficial fascia next claims our attention. In recent hernia, and especially in the congenital variety, except in so far as it to some extent guarantees the blood-supply of the aponeurosis beneath, this structure is of small importance in the surgeon's eye, but in herniæ of years' standing, and particularly in the herniæ of old men, it becomes a tissue of considerable strength and definite utility in helping to make the best of a bad job. There is no occasion in a young hernia to strip it from the aponeurosis as far down as the ligament; its incision in the same line as the division of the aponeurosis with which it has vascular connexions is sufficient. In older and large herniæ where it has attained greater strength and substance it may be incised nearer Poupart's ligament than is the aponeurosis and by judicious trimming may be used as an accessory layer of moderate but undoubted restraining power and this in cases where the more definitely fibrous structures in great degree fail the surgeon. In old cases all the other fibrous coverings and structures lose in tone and texture whilst this deep layer of the superficial fascia alone gains in strength and importance.

It is, however, often necessary to dissect up a little of this deep layer in order to choose a line in the aponeurosis of the external oblique which seems to invite separation. The aponeurosis should be separated or divided half an inch at least above Poupart's ligament—i.e., away from what is more or less a fixed margin. This leaves a good fringe of fibrous tissue attached to Poupart's ligament which enables the deep sutures to be more easily inserted into that ligament and removes them from the immediate line of the superficial stitches in the aponeurosis. It must be wrong to cut fibrous structures if we can possibly avoid it and a small linear hiatus in the spread-out aponeurosis can generally be found which lends itself to the exposure of the underlying muscle

with a minimum of actual cutting of aponeurotic fibres. The grain of the flat tendon of the external oblique ring generally travels in the direction in which we wish to divide it, so that even if a hiatus is not present the linear fibres can be separated with care in such a way as to produce very little real damage. I say very generally because whilst this obtains in young herniæ the line of the fibres is in old herniæ often curved by the bulging and not in consonance with our line of incision. This is one of many reasons why our attempts at radical cure in old herniæ are not comparable with our results in recent ruptures. In addition to this the lower fibres of the external oblique aponeurosis are more curved in some young cases than in others presumably with the less or greater obliquity of Poupart's ligaments, which is, after all, only their thickened and reinforced edge. Thus it is in a few young cases necessary to cut across fibrous tissue in exposing the internal oblique quite apart from those discrete transverse or intercolumnar fibres or bundles of fibres which may be met with far away from the pillars of the ring. We cannot but divide these cross fibres when we meet with them running more or less at right angles to the line of our incision or separation, but can we save the most important of them all, the external ring itself? If we divide the ring no suture, however deft, will make it nearly so strong as before. We divide fibres the integrity of which we can never replace. Up to this point we have been as careful of the parietes as we are in the operation of the removal of the appendix, and the structures to be dealt with, even the occasional cross fibres, are the same, but the ring introduces a new element altogether. It can, however, be ignored in two ways, each of which may be used in a certain number of cases. The division of the aponeurosis can be taken outward an inch or two inches or more beyond the internal ring. This does hardly any damage to the wall (as we follow up the hiatus or fissure and the cross fibres are fewer the further out we go) and it gives us much more room to manipulate the cord, so much so as to enable us to free the sac, even when scrotal, without division of the ring. So desirable a conservation is not to be attained in every case, but it may be in a very considerable number of cases. It is easily accomplished in large old herniæ, in which it is of great value. Even in cases of old men where the testicle is sacrificed in the hopes of patching up the abdominal wall sufficiently to make their lives endurable the ring is a valuable collection of fibres in a region where all the fibrous structures have given and sagged. In young subjects where all the tendinous material is tauter we may occasionally have to divide the ring to give us room to carry out our manipulations in the canal, but it is a sorry spectacle in a plastic operation to see fibres of such consequence divided and the awkward flap which results.

In strangulated cases it is now my practice, unless the patient's condition is very bad, to open up the canal at once after incising the skin in the position described for the radical cure. Our objective is the same in strangulated as in non-strangulated cases, so that there is no need for a different incision. When the field of our efforts—viz., the inguinal canal—is open by dividing or separating the aponeurosis, it does not matter how large the hernia below is, as everything can be pulled up into the opened canal immediately beneath the surgeon's eye and finger. By opening the canal in strangulated cases at once the surgeon is in complete command of everything which concerns the operation. The distended sac at once bulges into the division of the aponeurosis and can be easily opened, the contents in most cases can be gently disengaged and brought up from the lowest parts of the sac, the whole field washed from any fluid which ought not to go back into the abdomen and all without dividing the most important cross fibres of the part of the aponeurosis which we are dealing with—namely, the external ring. Before we divide the aponeurosis the ring is grossly stretched but directly the pressure of the aponeurosis and the sac is removed all tension on the ring is gone. Even when the external ring is the seat of constriction the bowel can be disengaged from it by working from above in the opened canal. Our division of the external oblique aponeurosis is in the direct line of its action, so that when the muscle acts the slit in the tendon is still more closely approximated, but if the ring has been divided the lower *point d'appui* of a number of muscular fibres (and these attached to the tendinous fibres nearest Poupart's ligament and therefore the most important in a hernial sense) is lost. The division in the line of action of the tendinous fibres even up to the muscular edge in no way interferes with the mechanics of the part, but the destruction of the ring throws out of restraining action a number of fibres and renders them divulsive. The care with which nature has reinforced and attached the margins of the ring shows us the light in which it may be regarded as an antagonist of intra-abdominal pressure. We also know that when our operation fails to be a radical cure the protrusion in most cases comes directly out of the abdomen in the vicinity of the damaged external ring. Thus an effort, I believe, should be made to spare the ring, a consummation I find much easier and more often accomplished now than when I first essayed it. In this my technique has been much helped by separating the external oblique aponeurotic fibres far out and by a recognition of the way of dealing with the cord and sac in the least disturbing and damaging way.

We may obviate the necessity of opening up the ring by taking our incision in the aponeurosis above it so that it is displaced downwards with what we may call the lower flap. In this, however, we cut through some valuable fibres lying across our path, which injury is to some extent remedied by the good raw surface left allowing of excellent apposition. Very satisfactory results have been got in the cases in which I have used this detail, but it is not to be thought of if we can do what is necessary by separating the aponeurotic fibres outwards for a considerable distance and sparing the ring. This is undoubtedly to my mind the ideal way of treating a hernial case and is strictly comparable with the ideal operation for gaining access to the appendix where only skin, a deep layer of superficial fascia, and peritoneum are incised. Having separated the long fissure in the aponeurosis the forefinger is passed inside the lower part and gently pushed along as low as Poupart's ligament. In some cases where the hernia has been in existence for some years and the other parts are becoming lax, the ilio-inguinal nerve may be pushed downwards by the finger rather than remain in contact with the cord. The internal oblique is now inspected critically, the assistant raising the upper edge of the external oblique, for upon its condition depends much of the further steps of the operation. The muscle dominates the situation entirely. Its variations are most remarkable. In the cases which lend themselves most perfectly to a radical cure—viz., those of adolescents and young adults with sacs which have been but little used—it is hard to see where a hernia can come down, so closely aggregated are the fibres arising from Poupart's ligament. In these cases we have to make a deep dive with the forefinger to get under the fibres arching over the cord and lift it into view. The internal oblique here, in fact, presents a complete muscular curtain continued and carried out of sight by the cremaster. In a less ideal case, yet one very adaptable, the curved fibres are seen arching across the cord with a very well-defined lower edge. From such as these cases descend in degree of eligibility till we find them where hardly any muscular fibres are arising from Poupart's ligament at all, where there is no lower edge demonstrable in the position where the arciform fibres should be and where the muscle present is definitely cremasteric. A case is thus eligible for radical cure in proportion to the abundance of muscular fibres arising from Poupart's ligament. A muscular curtain forms a live barrier to the intra-abdominal pressure while fibrous tissue is but mechanical. Nature has given us a happy combination of both. The mechanical always remains with some degree of tension, but the live barrier may have entirely disappeared, and in such a radical cure operation is but a patched up stop-gap proceeding at the best. On the other hand, where the living curtain is in good order and of decent size the surgeon can leave his patient with an abdominal wall almost without a blemish and practically as good as in an individual with no rupture or any tendency to it.

Having demonstrated the inner aspect of the external oblique aponeurosis (as far as it is in connexion with the canal area) by sweeping away the scanty areolar tissue with the forefinger the next step is to lift the cord partly out of its bed. It is unnecessary to separate the fibres of the cremaster or to open the infundibuliform fascia, and by so doing the nerve is in much danger of being divided. The left forefinger is dipped beneath the cord to the inner side of the centre of the canal and at the same time the edge of the arciform fibres is lifted gently upwards and outwards by a blunt hook in the hands of an assistant. Any cutting of the fibres of the internal oblique is, to my mind, a most mischievous proceeding, quite opposed to the principles which

should govern the operation of opening the abdominal wall. The forefinger pushed below the cord and then upwards thins and spreads this out so as to bring into view the denser tissues of the sac. It now shows in the same position as does the tense sac in a strangulated hernia. It is quite unnecessary, at this stage at all events, to push the finger right through; all that is wanted is sufficient pressure to enable the sac to be demonstrated and seized with forceps. The infundibuliform fascia can be torn through with two pairs of dissecting forceps and the sac gently eliminated without the cord (which has undergone a minimum of disturbance) having been entirely dislocated from its bed. This attacking of the sac above and behind is of importance. It guarantees the integrity of the nerves in front, it does not fray out the cremaster, and it enables veins to be lifted by dissecting forceps off the sac which is plainly shown and can be disengaged from the surrounding parts without damage to the veins. There is less inclination to strip the veins and other structures from the sac instead of loosening the sac from them. With the acquired sac and with a funicular sac which has closed somewhere in the canal the sac may be picked up anywhere by the manœuvre just described, though of course the lower margin of it is the easiest to pick up, but when dealing with a congenital sac—namely, a sac extending to the testicle (the curved lower extremity will, of course, not be seen) by far the readiest and best way of eliminating the sac from the cord is to begin high up near the deep epigastric artery. There the serous membrane is not so intimately associated with the cord and the vas deferens will allow the sac to be much more easily dissociated from it than lower down. If it is attempted to separate the congenital sac low down in the canal the surgeon will generally find himself after a time with shreds and streamers of serous membrane instead of the tube of sac which he will preserve if the elimination is started up above as near the point of divergence of the constituents of the cord as possible. In any case the sac must be cleared up to the level of the artery. A small pad of fat is very generally met with (even when there is but little in the cord lower down) just below the level of the epigastric artery. It runs up between the artery and the sac and may be continuous with the fatty covering of the bladder. It has a peculiar consistence and is, I believe, as a rule not at all closely attached to the sac. I have come to look for it in every case. It should be inspected carefully, as there are always possibilities of the bladder itself being in close juxtaposition. I like to see or feel the deep epigastric artery, but this aforesaid pad of fat is a very good landmark when it is small and quite differentiated from any fat in the cord. Some traction is made upon the sac when its elimination from the cord is completed, the pad of fat is gently disengaged, and the sac is tied with catgut just below the point where it is becoming parietal peritoneum. When the sac is thin and of little volume, the internal ring small and in proper position, and the muscular curtain of internal oblique sufficient the ligature need only encircle the small calibre of the sac and not transfix it. The part to be removed is cut short and with the release of tension the butt-end retreats rapidly behind the deep epigastric and disappears under cover of the muscular wall. This elasticity shown by the peritoneum is always encouraging, as it ensures that the previous point of exit of the hernia is well out of the way of the internal ring and that it has in front of it the vital force of the muscular curtain and not fresh scar tissue induced by the operation. Any small puckering, any slight inclination to pouching, does not matter if the pucker is supported by a sufficiency of muscle which when acting shuts down on the only possible place where pouching can become actually hernial. When a satisfactory muscular curtain exists deep Bassini sutures must be not only unnecessary but actually harmful, throwing the muscle in action out of gear and preventing it from forming an evenly-resisting barrier to the internal pressure. Thus in cases where the anatomical conditions lend themselves to a radical cure the surgeon may perform an operation which, while destroying no structures in the attainment of its end, removes that which is useless and harmful and leaves the part in the normal condition without any artificial additions.

In this operation, which can often be performed in adolescents and young adults, the skin is cut, which is harmless, and the sac is removed, which is needful. Nothing else is interfered with more than very slightly and temporarily. The points which I would urge are the skin incision well above Poupart's ligament and well away from the pubes, the separation of the fibres of the external oblique aponeurosis at a suitable spot, the separation being carried well towards the muscular portion, the sparing of the external ring, the dislocation but partial of the cord from its bed, and the elimination of the sac from above and therefore the preservation of the nerves, the whole to be accomplished with little or no bleeding—an advantage to be attained with great gentleness and the use of dissecting forceps. Apart from the unworkmanlike appearance of a sloppy operation area, bleeding much inconveniences the surgeon and damages the tissues. It obscures the view, necessitates constant sponging, and irritates the delicate areolar planes, which become more or less loaded with blood not capable of being removed. The serous exudation is much greater and the tissues are much weaker and sodden. In addition to these immediate disadvantages there is the grave though unlikely occurrence of thrombosis in the veins of the cord with its possibilities of pneumonia and other distant disasters. The absence of the deep sutures is a gain in two directions: the unimpeded muscle acts as nature meant it to, and there is no foreign body at all in the depths of the wound, no silk with tension on it, and no over-chemicalised catgut.

Unfortunately not all herniæ are susceptible of these innocent measures, but those which are, and they are an increasing number since subjects present themselves so early in life now, allow the surgeon to consummate an operation which in its aim, in its method, and in its results is practically perfect.

Melbourne, Victoria.

IMPERIAL BRITISH PHARMACOPŒIA: NOTES ON SOME INDIAN DRUGS.[1]

BY WILLIAM MAIR, F.C.S.

IN response to an invitation from the distinguished President of the British Pharmaceutical Conference to indicate which of the more important unofficial drugs indigenous to British India and in actual use by native and European physicians would be likely to present features of practical interest and utility to pharmacists in this country and to pharmacists generally the following brief details are submitted. I should add that my experience is limited to Calcutta, which may be taken to be fairly representative of the Bengal Presidency, and the drugs which I propose to deal with are well known throughout India. The promised early publication by the General Medical Council of an Indian and Colonial Addendum to the British Pharmacopœia of 1898 (which is expected to be authorised for issue by the end of the present year) and the consequent completion of Professor Attfield's worthy ideal of the expansion of that volume into an Imperial British Pharmacopœia suggest the desirability for some acquaintance with such of its probable contents as may be useful to pharmacists outside those portions of the empire for the special use of which products and preparations are to be officially recognised. Of the 40 or 50 medicinal substances and the practically corresponding number of pharmaceutical preparations the greater part (about 30) represents those requested by India and incorporated in Professor Attfield's Draft Addendum, now proceeding to a final draft through the hands of influential experts in India.

The question that has presented itself to some practical pharmacists is whether any or all of these drugs are likely to come into use in medicine in this country and which are likely to be worthy of attention that have been proved to be good for specific purposes in the land of their origin. It is not unnatural to expect that the great British dependancy which has given us nux vomica, cannabis indica, sandal wood, and kino and chiretta should still possess the secret of others of equal individuality. Whether that is so or not, whether there are lurking in the bazaars drugs of subtle action or potent virtue calling for a wider sphere of influence, it may not be for me to express an opinion. There are drugs in everyday use in the districts, as distinguished from the Presidency cities, the names of which even are not known to Europeans, but it is hardly possible that any of

[1] A paper read before the British Pharmaceutical Conference on July 25th, 1900.

equal value to those which I have indicated or any drug of therapeutic interest not already represented in the Pharmacopœia could have escaped the notice of observers and investigators.

To proceed to the analysis of the 30 medicinal products of India likely to be included in the forthcoming Addendum as a selection bearing the stamp of official approval there fall to be eliminated those that are intended for use in India only as local substitutes for, and alternatives of, the official imported products. It does not directly concern us how far calumba could be replaced by coscinium, its former arch adulterant; whether the wood of samadera would equal that of quassia, unless the latter were becoming scarce and dear; how far the root bark of toddalia may represent casparia or cissampelos would pareira; to what extent the leaves of datura alba are equivalent to those of belladonna in terms of the relationship of daturine to atropine and hyoscyamine; whether also cotton-root bark will make an infallible substitute for ergot; or whether the telini fly will not yield more cantharidin than the true cantharides, or the very doubtful tylophora leaves or the root bark of calotropis (mudar), both advocated for many years but never used, supersede the indispensable ipecacuanha which, unhappily, has not yet been successfully cultivated on a commercial scale in India. Few of these alternatives are likely to acquire much significance to pharmacists outside of India or to importers. Butea gum may come to be recognised in this country as in some measure, though very imperfectly, representing the official kind, in which case the question presents itself whether the use of the Addendum may not be reciprocal and whether those country medicines to be recognised for use in India instead of the imported drug may not be officialised for use in this country in time of scarcity. There are others, however, of more strictly commercial importance which would be better considered from that point of view, but for which recognition is desirable for the adjustment of official standards. These are gummi indicum (dhaura gum), when clean and good quite equal to gum acacia; the oil of gingeli seed (sesame oil), exported from India in oil and seed to the value of nearly £1,000,000 sterling per annum, approximating to olive oil; and oleum arachidis (nut oil), proposed to be "employed in Indian pharmacy whenever olive oil is ordered in official preparations," to quote the words of the Draft Addendum. Wherein the question of reciprocity would again arise. It is fortunate that many important points of chemical, physiological, and therapeutical detail in reference to these articles will now be finally settled by the committees entrusted with their pharmacological investigation, but it has to be said that some of the alternatives proposed which have most probably, however, been subsequently reconsidered are not known in actual use, and it is difficult to understand why, for instance, crinum bulbs should have been recommended for use instead of squill, while no mention has been made, so far, in any of the published reports of the bulbs of either urginea indica or of ledebouria hyacinthoides, the squill of the bazaars, largely and regularly used in Government dispensary practice. I omit also from consideration at this time betel leaves and jasmine flowers, both used in the fresh state for purely domestic purposes.

The following may be found to be worthy of a more definite place in medicine in this country; some are old friends seeking re-introduction. They would repay attention and trial in the conditions indicated. I ought to state here that it was my intention to have accompanied this paper with formulæ and processes for the preparation of each drug which I would consider most suitable. It has not been found possible, however, to complete the long series of experiments necessary to arrive at reliable data. The details of these processes will appear in full, however, in this paper as published in the Year Book of Pharmacy.

Andrographis paniculata (the kreat, the dried herb; shown).—Perhaps this is the most worthy of recognition of the many simple bitters of India, in addition to chiretta, not as a substitute for it. One of its vernacular names implies "king of bitters." It contains a neutral non-alkaloidal bitter principle as yet unnamed and has febrifuge properties which chiretta does not possess. For that reason it is appreciated in India and is frequently prescribed in convalescence after fevers; it has been employed successfully in influenza. Fluid extract. (A formula will appear in the extended paper as published in the Year Book.)

Belæ fructus.—Although tried in this country and found wanting the sacred bael is, as it has always been, the most trusted of Indian indigenous medicines. It is constantly prescribed by European physicians and is of unquestionable value in diarrhœa, avoiding, especially in children, the constipation attending the use of astringents. An aqueous fluid extract from the pulp of the fresh half-ripe fruit, instead of that "imported in dried slices" will redeem its character. Another preparation in great favour in India is a confection of bael, sometimes aromatised, a valuable dietetic in teaspoonful doses in chronic diarrhœa, made from the pulp of the fresh just ripe fruit freed from the seeds by passing through a coarse sieve and preserved with sugar. For the extract the fruits, freshly imported whole, would require to be used; the confection would be best prepared on the spot and imported after the manner of tamarinds and chutnies.

Ispaghula (seeds of Plantago ovata; shown).—These minute boat-shaped seeds are imported from Persia. They contain no medicinal principle whatever but are peculiarly successful as a remedy in diarrhœa and dysentery and as an intestinal emollient in gastric catarrh. The simplicity of their action is such that no preparation can be suggested. One drachm of the cleaned seeds is infused for 20 minutes in five ounces of cold water, sweetened with sugar, and the resulting mucilaginous mass is swallowed unstrained. The action is purely mechanical, the abundant, bland, adherent mucilage allaying the intestinal irritation. They are employed in the manner indicated by distinguished officers of the Indian Medical Service.

While this paper is in no sense a criticism of the published material proposed for the Addendum, the limit of time for the presentation of comments and suggestions as invited by the editor (significant of a new era in Pharmacopœia-making) having passed, I cannot refrain from expressing the hope that some of the following may have been deemed equally worthy of recognition with the foregoing.

Holarrhena antidysenterica (kurchi, root-bark; shown).—This, perhaps, comes next to the bael in the estimation of European prescribers in India among indigenous medicines. The active principle is the alkaloid kurcheine and the properties are mildly astringent, anti-dysenteric, and febrifuge. Both a solid and liquid extract are used in India, the latter being the more desirable. (A formula and process will be presented in the Year Book.)

Garcinia Mangostana (mangosteen rind; shown; imported from Singapore).—This drug contains tannin, resin, and a yellow crystallisable principle, mangostin, and is used popularly like kino or catechu, but not much prescribed, in the form of a syrup made by boiling the rind in water and adding sugar to the strained decoction. A better process is to make the syrup from a fluid extract from 20 per cent. alcohol.

Carica Papaya.—The importance of the papaya fruit [shown] cannot be over-estimated, and it may be found to have been given a place in the ultimate Addendum for the sake of the well-known papain, as an alternative to pepsin, if only on the ground of caste prejudice. An elegant liquor papain which is made from the fresh milky juice and preserved with glycerine is also in vogue as a successful "vegetable pepsin." Its action is, of course, distinct from that of pepsin.

Eugenia Jambolana (jambul seeds; shown).—If this drug has not fulfilled all that was expected of it as a remedy in diabetes it remains to be disproved whether it is not of use in the treatment of diabetes. All that need be said is that it is used by the people and prescribed by distinguished native physicians. The secret may perhaps lie in making the aqueous liquid extract from fresh seeds from ripe fruit.

Gynocardia odorata (chaulmugra seeds; shown).—The value of the expressed oil in eczema, psoriasis, and allied skin affections is too well known to call for comment. It is regularly and largely prescribed for external use and in the style of a cream with equal parts of the oil, lanolin, and lime water.

Adhatoda vasica (leaves shown).—This drug is used in pulmonary affections and is regarded as an internal antiseptic in phthisis. It contains a white crystalline alkaloid-vasicine, sparingly soluble in water but soluble in alcohol. The drug is strongly alkaline, due to the presence of potassium chloride. The only preparation which I have seen prescribed is syrup vasak, which is best made from a liquid extract.

I have the honour to acknowledge my indebtedness to Professor Wyndham R. Dunstan, F.R.S., for authentic specimens from the Imperial Institute collection; to Mr. E. M. Holmes, F.L.S., for other specimens; and to my friend Mr. Frederick Bascombe, F.I.C., for undertaking and

carrying through the pharmaceutical work involved in the laboratories of Messrs. Fletcher, Fletcher, and Co., Limited, to whom also my thanks are due.

Edinburgh.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON THE SAFEST METHOD OF REMOVAL OF THE APPENDIX.

BY A. A. WARDEN, M.D. GLASG. AND PARIS,
ASSISTANT, DR. DOYEN'S SURGICAL CLINIQUE, PARIS.

APPENDICITIS has become so frequent an alarm in daily practice and is so treacherous in its behaviour that surgeons would do well to be agreed upon the method to be followed when removal of the appendix is decided upon. There are at present three methods in use which I venture to term (1) the continental method; (2) the English method; and (3) Doyen's method, which is best because it is the simplest and safest, and which I call Doyen's because I believe Doyen to be the first surgeon who has described and used it.

1. The continental method—that commonly followed by Terrier, Hartman, and most Paris surgeons—is simply to ligature the inflamed and diseased appendix near its base, resect it with the thermo-cautery, cauterise the stump, and then let it fall back into the abdomen. This method must be admitted to be faulty because it leaves loose and open in the abdomen the cauterised lumen of the appendix which, even if effectively cleansed, is almost certain to adhere to neighbouring abdominal contents. If ineffectively cleansed pus and a peritoneal abscess (and perhaps generalised peritonitis) are inevitable.

2. The English method, associated with the names of several surgeons, is to dissect back a collarette of peritoneum which is finally stitched over the ligated stump of the appendix. This method is an improvement on the former one but is also faulty in being more difficult and in exposing the field of operation to a leakage of the bowel contents in the event of an accidental puncture or opening of the appendix. In the case of an inflamed and diseased appendix this accident is difficult to avoid if attempts are made to strip off the serous covering.

3. Doyen's method I consider to be the best because I see no valid objections to be urged against it. It is simple and rapid; the appendix is not opened, so there is no possibility of infection of the peritoneum by escape of bowel contents; and lastly, by invagination of the stump, in the event of further infection and suppuration the pus is bound to discharge into the lumen of the bowel and to be evacuated naturally per anum. I will describe the little operation briefly, step by step. The little mesentery of the appendix is first ligatured with a small silk ligature to free the appendix laterally. Then (1) the base of the appendix is gently crushed with Doyen's small clamp. Almost any forceps suffices for this purpose if strong enough and broad enough to completely occlude the appendix for a breadth of, say, a quarter of an inch; (2) a fine silk ligature is thrown round the base of the appendix in the furrow left by the clamp; (3) the appendix is then removed by the thermo-cautery cutting close to the ligature; (4) a purse suture is then made in the serous covering of the cæcum close round the base of the appendix (as this purse stitch is drawn tight the little stump is invaginated so that all is completely closed); and (5) for safety a second fine silk purse stitch is made and the little pucker of the first stitch is similarly invaginated and the ligature is gently tightened. The result technically is perfect and certainly this is the most aseptic method of removing the appendix.

Mr. C. B. Lockwood in a recent article[1] entitled "The Organisation of Aseptic Operations and Some of the Causes of Failure" refers to 10 cases of operation for appendicitis in which no pus was found and yet in which the abdominal wound suppurated in three cases with extrusion of some, if not all, of the sutures. He came to the conclusion that some of these failures were due to the nature of the operation and that, as a matter of fact, the wounds became infected during the removal of the appendix. Mr. Lockwood adds that he has histological evidence that even in non-suppurating cases the inflamed tissues round the diseased appendix are often infected with bacteria and that, therefore, it is not to be wondered at that, after appendix operations, buried silk sutures are apt to be extruded. "I have not abandoned hope," he says, "that we shall learn how to bury silk in the abdominal wall in appendix operations." I venture to express the belief that this hope would be more speedily realised by the general adoption of this aseptic method of removing the appendix.

NOTES OF TWO CASES OF PERNICIOUS ANÆMIA TREATED WITH HOMMEL'S HÆMATOGEN.

BY HERBERT MEGGITT, L.R.C.P., L.R.C.S. EDIN.

CASE 1.—A man, aged 35 years, came to me in February, 1899, complaining of giddiness, shortness of breath on exertion, and general languor. His skin was of the peculiar lemon tinge so often seen in these cases. The patient had not lost flesh and in fact he thought that he was stouter than formerly. Inquiry elicited the fact that he had had a family worry some time previously and that he had never felt the same man since. He had begun to feel weak and unable to exert himself and his friends at the same time began to notice his increasing pallor. The urine was high-coloured but free from albumin. The ordinary causes of anæmia were carefully eliminated and the case was diagnosed as one of pernicious anæmia. An examination of the blood resulted in the discovery that its specific gravity was reduced 1040. The corpuscles did not adhere in rouleaux and their number was greatly reduced, but what was most noticeable was their great variation in form and size; nucleated red corpuscles were also present. Arsenic in gradually increasing doses, in the form of Fowler's solution, was given and continued for some time, but with absolutely no good effect. At the commencement of this treatment the patient was kept in bed. The diet ordered was chiefly farinaceous. Iron was then administered, but with like results. The patient was evidently getting weaker. Happening to mention the case to a friend he advised me to try Hommel's hæmatogen. It was given daily with the best results for four and a half months. A further examination of the blood showed that the corpuscles were assuming their natural shape and their number had increased, but the more tangible and satisfactory result was the condition of the patient who was able to resume his work with a freedom from all his previous symptoms.

CASE 2.—This case was interesting from the fact that the patient had been treated with salol after the failure of arsenic with marked improvement, but unfortunately with a relapse. The patient was a woman, aged 38 years, who complained of faintness, palpitation, loss of appetite, extreme debility, and constant vomiting. The pallor of the skin was striking. The mucous membranes were pale, there was œdema over the malleoli, and there were some petechial hæmorrhages on the lower limbs. It happened that the patient when residing elsewhere had been under treatment for the same condition and she thought that she had been cured, but after a period of four months the old symptoms returned. Correspondence with her previous medical man revealed the fact that she had been treated with arsenic and later with salol with apparent benefit. I therefore determined to commence the treatment with the administration of Hommel's hæmatogen. This was continued on and off for a period of six months, during which time repeated examination of the blood was made, marked improvement being noted.

Tottenham, N.

A CASE OF SUDDEN DEATH SHORTLY AFTER OPERATION.

BY W. BOLTON TOMSON, M.D. DURH.

A SOMEWHAT delicate overgrown child, aged 12 years, was operated on for adenoids and enlarged tonsils at the Children's Hospital, Luton, on July 7th, at 3.20 P.M. Chloroform was administered through a Krohne's inhaler to start with, and later from the ordinary flannel facepiece.

The child was very nervous, and from the first did not breathe well, the colour and pulse, however, still keeping good. Chloroform was therefore purposely not pushed to complete anæsthesia, but the gag was introduced when voluntary movements ceased, there being still a slight corneal reflex. The tonsils were first removed, but as there was considerable struggling the head was drawn well over the edge of the bed, and a little more of the anæsthetic was given. The adenoids were then removed in the usual manner, the operation being followed by, if anything, less bleeding than usual. The child was at this time breathing well, and had to be held down, having partly recovered from the anæsthetic but not yet being conscious. Shortly afterwards the colour suddenly changed, the respiratory movements became feeble and the pupils dilated, and the pulse grew very weak. Artificial respiration was immediately commenced by the Silvester method, the tongue was caught in tongue forceps and drawn well forward, injections of ether and strychnia were given, and hot-water bottles were applied between the thighs and to the soles. At first there was slight improvement, but spontaneous breathing never completely returned, though faint respiratory movement was perceptible for nearly three-quarters of an hour. The heart sounds grew fainter and fainter and finally ceased. Rhythmic traction on the tongue had meanwhile been steadily practised (as advocated by Laborde) and as a last resort, to obviate any possibility of laryngeal obstruction, tracheotomy was hurriedly performed. There was, however, no attempt at rallying and the heart sounds and breathing having ceased for some time artificial respiration was abandoned after about one and a half hours.

The immediate cause of death is not easy to state. As far as the anæsthetic was concerned it was Messrs. Duncan and Flockhart's best, and a remarkably small dose was given, only one and a half drachms (measured). Anæsthesia was, moreover, at no time complete. Further, after the operation had been concluded and the administration of the anæsthetic had ceased for some minutes, there was partial recovery, as evidenced by the struggling. The heart was carefully auscultated before the operation and no abnormality was detected. Of obstruction to the respiratory passages, such as might have been caused by spasm of the glottis, or accidental sucking in of blood there was at no time any evidence. Air entered and left the chest during artificial respiration with an audible noise, and there was no stridor. There was no intense cyanosis or venous engorgement, such as one might expect were asphyxia the cause of death, but only a lividity of the face and blueness of the eyelids, which varied with the success of the artificial respiration. There was no vomiting during the operation or subsequently. Under these circumstances, therefore, it seems to me to be probable that death was due to gradual cardiac paralysis.

Luton.

DEATH OF A CENTENARIAN.—The death occurred recently at Lapford, Devonshire, of Mildred Jerrett, who, according to the register at the parish church, was baptized in February, 1800.

THE LEAGUE OF MERCY: PRESENTATION OF THE ORDER OF MERCY.—Their Royal Highnesses the Prince and Princess of Wales, as Grand President and Lady Grand President of the League of Mercy, entertained the presidents and vice-presidents of the league at Marlborough House on July 27th. The guests assembled in the garden and on the arrival of the Prince and Princess were presented to their Royal Highnesses. During the course of the afternoon the Prince and Princess of Wales in accordance with the statutes of the league presented the Order of Mercy for services to the league, and also for services in connexion with the London hospitals, to the following: Sir Whittaker and Lady Ellis, Mr. E. A. Hambro, and Mrs. Herbert Allingham.

UNIVERSITY COLLEGE, BRISTOL.—A further addition has just been made to the structure of University College, Bristol. The new building, which closely adjoins the medical school, has been erected at a cost of about £6000. It contains on the ground floor a library about 46 feet square, also several class-rooms and preparation rooms for biological work. On the upper floor is an examination hall 88 feet long by 46 feet high and a gallery has been arranged at one end. The building is approached by an entrance in the front and lavatories and cloakrooms have been provided.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

SALISBURY INFIRMARY.

A CASE OF CEREBELLAR TUMOUR IN WHICH THE RESPIRATION WAS ENTIRELY SUSPENDED FOR FOUR HOURS BEFORE CESSATION OF THE CIRCULATION.

(Under the care of Dr. E. T. FISON and Mr. L. S. LUCKHAM.)

A YOUTH, aged 16 years, was admitted into the Salisbury Infirmary on Feb. 3rd, 1900. He complained of great pain in the head, back, and heart, and of vomiting. He had been in bed for the past three weeks, and had been sick after all solid food. His sister stated that during the paroxysms of pain he became quite rigid, but that he was not convulsed. For some time previously to this he had suffered from constipation and headache. The appearance of the patient was dull and apathetic, and he was of a dusky leaden hue, and looked markedly the subject of cerebral disease; at times he appeared to be in pain, when he called out and complained of his head. The tongue was thickly coated. The temperature was only 97° F. and remained subnormal throughout, the respirations were 16, and the pulse was 70. His attitude was one of general flexion and he kept in a lateral position; the head was much retracted and on extension of the neck he called out with pain. He was very irritable and objected to be roused, and at times feigned to be asleep. There was no strabismus, but the mouth was drawn up slightly to the right as though the left buccinator was a little paralysed. The tongue was protruded straight. The abdomen was retracted. The hand-grasps were equal and there was no paralysis of any other muscle; the knee-jerks were at times present and at others were absent. Kernig's sign was absent. Sensation was normal. The bowels were obstinately constipated. The urine contained no albumin or sugar. There was nothing abnormal seen in either ear. The ophthalmoscope showed marked papillitis with considerable swelling, estimated to be about 4 D. There were also some hæmorrhages. The left optic disc seemed more inflamed than the right. The vision was $\frac{6}{9}$ in both eyes. There was nothing distinctive about his gait as he was so weak that he could hardly stand alone.

For a few days after admission he kept his back arched and at times he had pleurosthotonos with the concavity to the left, but his general position was on the right side. He was only occasionally sick. He often called out with the pain in his head, but it was more of a moan than the piercing cry of meningitis. He generally located the seat of the pain to the left side of the back of the head. On Feb. 8th he had an attack of rigidity of the limbs and trunk lasting for three or four minutes. At times he was more drowsy than at others and the facial paralysis varied also considerably, sometimes being absent. On the 12th a consultation of the staff was held and the general opinion expressed was that the patient had a cerebellar tumour, and Dr. Fison ventured to locate it in the left lobe of the cerebellum and thought that it was probably a tuberculous tumour. An operation was decided upon, but before it was done it was decided to increase the iodide of potassium to 15 grains, it having previously been given in smaller doses. This delay was unfortunate, as instead of improving the patient steadily got worse. The pain increased, he lost control of the sphincter vesicæ and the sphincter ani, and an operation was definitely decided upon for Feb. 22nd.

At 9.30 A.M. on that date chloroform was given by the open method. There was no corneal reflex, the pupils were contracted, and he appeared to be semi-conscious before the administration of the anæsthetic was commenced. At 9.50 A.M., Mr. Luckham operating, a crescentic skin incision was made behind the ear, having for its centre a point one and a half inches behind the centre of the external auditory meatus and a quarter of an inch below, when the patient was noticed

be turning very livid. About one and a half drachms of chloroform had been used, but the anæsthetic had been discontinued for some minutes previously. As the lividity was increasing the tongue was drawn out and artificial respiration was begun, and during the next four hours till his death at 1.40 P.M. he was kept alive by artificial respiration, on cessation of which he at once became livid again and the pulse became imperceptible. During the whole period the pulse varied considerably, at times being imperceptible, at others 80 per minute and of good volume, and at others 140; of true respiratory action there was none, the only approach to it being an occasional reflex action of the pharyngeal muscles. The battery was applied to the præcordium and to the phrenics and diaphragm. Strychnine and brandy were injected and the external jugular vein was opened.

Necropsy.—At the post-mortem examination on the next day, on taking off the skull-cap there was found to be great tension of the dura mater; on removal of the brain a large amount of cerebro-spinal fluid was seen at the base of the brain, at least five ounces together with what was in the ventricles. In the left lobe and at the edge of the cerebellum a hard mass was felt. This mass on section was of about the size of a penny, fairly circular, firm to the knife, and yellowish-grey in appearance; around the tumour there was a fibrous capsule, and exterior to this there was a ring of red softening, so much so that it was possible easily to lift the growth from its bed. It was not made out definitely that it pressed upon the seventh nerve, but doubtless it could have done so in that position. The lateral ventricles were very much dilated and the foramen of Monro was large and the veins of the choroid plexuses were much engorged. In the chest there were many old adhesions of the pleura, especially on the left side. Nothing else abnormal was found in the body but a few large mesenteric glands. Dr. C. Slater of St. George's Hospital kindly examined the growth microscopically, and reported: "I think the tumour is undoubtedly tubercular, and I have found bacilli unmistakeable but very scanty—one or two per section."

Remarks by Dr. FISON.—The diagnosis of the above case presented no marked difficulties if the signs and symptoms could be definitely relied upon. The first question arose, Was it meningitis or tumour? This seemed to be easily answered, as the case had been of too long duration for a tuberculous meningitis; still, there are rare cases of chronic hydrocephalus which come on as a result of posterior meningitis and which present the same signs as tumour. Passing to the more difficult matter of its localisation the signs seemed to point to a tumour in the cerebellum; this was shown by the retraction of the head, the attacks of bilateral rigidity and persistent posterior pain, and also by the great swelling of the optic discs, cerebellar tumours causing more intense papillitis than tumours in the hemispheres. Having located it in the cerebellum, which of the three lobes was it in? There was no vertigo or reeling in walking which is associated with growths in the middle lobe, and the fact that the left facial nerve was involved seemed to point to the left lobe, this nerve presumably being involved in its course to the internal auditory meatus. Facial paralysis also is generally on the same side as the lesion in the case of tumour. It did not seem probable that the nucleus was involved, as it would be difficult then to understand that one cranial nerve should alone be involved. It would seem strange that the auditory nerve should be unaffected, but it is an observed fact that sensory nerves are capable of withstanding more pressure than motor (e.g., crutch palsy—paralysis in Pott's spinal disease). Besides this the boy complained constantly of pain in the left side of the back of his head. As to its nature this could only be surmised; there was no history or sign of syphilis, and no improvement took place under iodide of potassium. But considering that tuberculous masses form the bulk of cerebellar tumours in the young, it seemed probable that this was a tuberculous growth. Thus Allen Starr, out of 299 cases of tumour in patients under 19 years of age, found that 152 were tuberculous.

This mode of death in tumour of the brain receives but little notice in the text-books on medicine. Thus Byrom Bramwell in Allbutt's System of Medicine makes no mention of it; he says, however, that Cheyne-Stokes breathing occasionally occurs, particularly when the tumour is near the respiratory centre. Hilton Fagge says that death is often caused by cessation of the respiration, and in one instance the pulse went on for 35 minutes after the respiration had ceased. The other works on medicine which I have been able to consult make no mention of it at all. I know, however, of a case that occurred in the Hospital for Sick Children, Great Ormond-street, where respiration failed 30 hours before death ensued, artificial respiration being kept up for the period. I am told, also, that at the National Hospital for the Paralysed and Epileptic, Queen-square, this condition is by no means rare.

I have been able to come across only one paper in literature relating cases; this is by Sir Dyce Duckworth.[1] He reports four cases of cerebral disease in which the respiration ceased for some hours before the circulation. The first two cases were the subjects of abscess, one in the cerebellum and one in the temporo-sphenoidal lobe. Both were trephined, and in neither was the abscess opened; in neither did the trephining restore the respiration which ceased three and three-quarter hours and four and three-quarter hours respectively before the circulation. In the third case, one of abscess in the temporo-sphenoidal lobe, at midday artificial respiration had to be resorted to, and as the patient improved an anæsthetic was given and trephining was done; the abscess was found and opened and the respiration much improved, death, however, occurred at 6 P.M. on the same day. The fourth case of the series is one of hæmorrhage into the brain and ventricles of slow onset; trephining was done, and about half an ounce of blood was withdrawn from the right ventricle without any effect on the respiration. The heart ceased five hours after the respiration. Professor W. Macewen operated upon and opened a cerebellar abscess in a subject whilst artificial respiration was being performed. The respiration soon afterwards became voluntary. Nicoll[2] reports a case of supposed temporo-sphenoidal abscess in which during the preliminary stage of trephining the respiration ceased and artificial respiration had to be resorted to. It was determined, however, to open the skull; this was done and the patient began to breathe. A large malignant tumour was found growing from the petrous bone. The patient lived for two and half months afterwards. Every experimenter[3] upon this subject has proved that increase of intracranial pressure manifests itself more upon the respiratory centre. This centre appears to be more sensitive and vulnerable to pressure, but not so vital as the vaso-motor centre. Thus, by pressing upon a meningocele children can be put to sleep and the respiration is slowed. In animals, intracranial tension experimentally produced slows, and then abolishes, respiratory movement before the heart ceases action.

It seemed possible at first that the patient was suffering from chloroform poisoning. This, however, on second thoughts seemed to be unlikely, as, though in death from chloroform respiration at times ceases before the circulation, yet there is no great interval between the two events. Chloroform poisoning in its later stages produces a fall of the venous cerebral pressure, this being due to a general fall in the arterial pressure, and also due to inhibition of the vasomotor splanchnic mechanism, so that the patient bleeds to death into the veins of the splanchnic area.[4] In this case the arterial pressure kept good so long as artificial respiration was kept up. From the cases quoted above it would seem far more likely that relief to the respiratory centre will follow if the abscess be evacuated or the tumour removed, it not being sufficient to remove only a crown of bone. The explanation is that in greatly increased intracranial pressure the bulb blocks up the spinal canal and no cerebro-spinal fluid can be forced out by the atmospheric pressure into the subdural space in the cord. What one certainly has learnt is that even though the respiration ceases the operation ought to be continued at all hazards, for there is certainly a chance of voluntary respiration returning if the growth be removed. I certainly regret that this was not done in this case, especially as the growth was exactly situated under what would have been the trephine hole, and it would easily have been shelled out. Whether this condition is more common in connexion with tumours of the cerebellum than of the hemispheres I do not know. At any rate it seems likely that respiratory failure would occur in an earlier stage of the growth or abscess, for, shut off as it is by the tentorium cerebelli from the fore brain in a small space, the effects of pressure must exert themselves sooner than in the case of growth in the larger space occupied by the hemispheres.

THE LANCET.

LONDON: SATURDAY, AUGUST 4, 1900.

WE publish in this issue three of the addresses delivered before the British Medical Association at Ipswich in plenary congress—namely, the Presidential Address of Dr. ELLISTON, Dr. PYE-SMITH'S Address in Medicine, and Mr. TREVES'S Address in Surgery. Dr. ELLISTON'S address was one to which he had evidently given time, thought, and knowledge, and with very happy results. In particular we are obliged to him for giving us in his brief review of the progress of medicine during the last two centuries the individual exploits of eastern county practitioners and savants. It is not the first time that Presidents of the British Medical Association have in their presidential addresses recorded the medical history of the locality where the congress is meeting, and we think that it is an example which other Presidents might well follow. The difficulty of finding themes upon medical and allied topics is now very acute, while the fact that we are at the close of the century has brought upon the medical world during the past 12 months an enormous mass of *résumés* of the progress of medicine viewed from general and all sorts of special standpoints—and as the century is not yet complete we may expect to meet with more addresses of similar scope and aim. Such summaries of medical and surgical knowledge, if only approximately exhaustive, make orations which are far too scrappy to be interesting to any audience, as those of us who have heard them and read them know. If Presidents of the British Medical Association will desist from attempting so large a programme as a general review of the progress of medical science, and will year by year address us from the standpoint of residents in the different medical centres of England, their contributions to our knowledge will be exceedingly welcome. In this way a complete history of the prominent members of the medical profession in the country will be formed and a hero-worship of the most practical sort will be promoted. For whereas a young man may feel that the fame of WATSON, GULL, or HUMPHRY—to mention three distinguished East Anglians—can never be his while he hears of their proud position in an enormous scientific hierarchy, he is not so certain that his own good work will of necessity go unrecognised when he learns the identity of his early environment with that of many medical heroes.

Dr. PYE-SMITH in his address deals with the well-known question as to whether medicine should be regarded as a science or an art, and we need hardly say that his contribution to the controversy is thoroughly interesting. "If," says Dr. PYE-SMITH, "medical science without art is inefficient, medical art without science is not only unprogressive but almost inevitably becomes quackery." In this sentence he seems to us to sum up the points at issue. Not that we would have had him briefer, for a good thesis loses nothing by being proved. Medicine, especially practical therapeutics, cannot be regarded as a matter of cold science. General rules cannot be laid down to guide us in treatment, except with a saving clause that the rules are so general that they must be freely departed from when sick individuals will not conform to the rules. The most logical deductions from chemistry and physics when applied to the mechanism of physiology, the most ingenious explanations of symptoms and sequelæ based upon what we regard as flawless pathology, have often failed to save life and will often again fail. For while one test-tube is the fellow of another, and one dead man behaves remarkably like another, every living individual is a bundle of complexes who refuses to be classified wholly and satisfactorily as a patient of a certain type, suffering from a certain condition, and bound to be relieved by a certain remedy. That many departments of medicine which were treated by older physicans as provinces of art have now become provinces of science is undoubtedly true; the etiology of much disease is clearer to us than it was to our forefathers, and the rational methods of prevention or cure have consequently followed. But there is still an enormous amount of work to be done and boundless experience to be tabulated and digested before the origin of many common pathological states becomes apparent and the treatment deliberately scientific. Here is where genius comes in, although Mr. TREVES is reported to have said that a medical man has no business with genius. It is genius which now and again shows us a short cut from art to science, cutting by intuition the knot that others, working according to routine, have failed to untie.

Mr. TREVES, who delivered the address in Surgery, took as his subject the contrast between the science and art of surgery in 1800 and the condition to which that science and art have attained at the present day and made somewhat dry bones speak by dint of a clear and breezy style. Mr. TREVES attributed the difference between surgery at the end of the eighteenth century and surgery at the end of the nineteenth century to four causes: an improved knowledge of anatomy, a readier method of arresting hæmorrhage, the employment of anæsthetics, and asepsis. There is no need to follow Mr. TREVES in detail while he asserts that the essential reasons of the modern extension of the fields of surgery are to be found in the employment of anæsthetics and antiseptic measures. The former has made the patient willing to undergo operations which would have been almost unendurable if he had retained his full senses, and has induced many to consent to operations who would have been unable otherwise to screw their courage to the sticking point. But, while the 40 years which intervened between the discovery of anæsthetics and the introduction of antiseptics witnessed great advances in surgical practice, the septic complications of all operations of every variety were so many and so serious that surgeons hesitated to perform operations which they knew would prove of great benefit if they should be successful, but which might end rapidly in death. The practical certainty given by the antiseptic treatment that no pyæmia or septicæmia would carry off the patient completed the value of the discovery of anæsthetics and revolutionised the practice of surgery. With regard to the value of the other two factors in the modern progress of surgery we are not so certain. The improvement in the knowledge of anatomy among the whole

body of the profession if great is only partial. It is probable that the average hospital surgeon in 1800 knew very little less of the anatomy which concerned his practice than the average hospital surgeon of the present day. No small portion of the anatomy that is now taught is perfectly useless from the point of view of the practical surgeon. The more ready methods we possess of arresting hæmorrhage make also a factor in the progress of surgery during the century which is of but little importance. The surgeons of 1800 stood in no great fear of hæmorrhage during an operation—we refer to primary hæmorrhage, of course. They applied the ligature freely, as may be seen in BENJAMIN BELL'S Surgery, the seventh edition of which was published in 1801. But they did fear secondary hæmorrhage, and rightly so, for all the ligatures or arteries were left long in order that they might come away when suppuration was fully established, and then it was that hæmorrhage often took place. The easily applied pressure-forceps of SPENCER WELLS and PÉAN are valuable assistants in a modern operation; and the much greater frequency of operations has perfected hospital surgeons in operative procedure. But for the rest, the progress of modern surgery is due to the discovery of anæsthetics and the introduction of antiseptics.

THRICE within his reign of not quite 22 years has King HUMBERT been marked down by political vendetta. In Naples, in the late autumn of 1878, when, with Queen MARGARET and the Crown Prince, he was making a Royal progress through the streets his life was attempted by PASSANANTE, but the blow fell not on His Majesty but on his faithful Minister CAIROLI, fortunately without fatal result. Again, in Rome, during the race meetings in the spring of 1897, he was assaulted on his way to the course by ACCIARITO, and again the assassin missed his aim. For the third attempt, at Monza, on the evening of July 29th, a change of weapon was tried, and the stiletto, the favoured instrument of the Italian regicide, was replaced by the hitherto untried revolver—this time with all too deadly effect. He was shot through the heart and died almost instantaneously.

Life is cheap in Italy, but King HUMBERT'S was, perhaps, the one she could least of all spare. An exemplary monarch, he inherited all his father's courage, though certainly not his father's centripetal insight into character or the conduct of affairs. His baptism of fire at Custoza in 1866 was followed up by many an act of public duty as devoted and as fearless. He seemed, indeed, to court danger and death itself in behalf of his subjects. In the appalling earthquakes in the island of Ischia in 1881 and 1883 he was conspicuous beyond even the most reckless of the relieving force in extricating man, woman, and child from under tottering edifices, the collapse of some of which had already proved fatal. In the destructive cholera epidemic in September, 1884, his absolute disregard of self is among the most beautiful passages of history. It was in Naples that the malady exploded with deadliest effect, and the KING was at the time at Pordenone in the Venetian territory, about to open a racecourse. Barely had the news come that in one night 2000 Neapolitans had been stricken down, and that of these 1000 had succumbed as much from panic as from the disease, when he addressed the Mayor of Pordenone: "A Pordenone si fa festa. A Napoli si muore. Vado a Napoli." ("At Pordenone there is merry-making. At Naples people are dying. I go to Naples.") And to Naples he went, and for more than a week he spent many hours of each day at the bedsides of the worst cases—so near to them, in fact, that several times within the 24 hours he had to retire and substitute fresh clothes for those which had to be burnt. Again and again the Ministers and even the professional men who formed his suite implored him to "think of his dynasty and the interests of his people," and his reply, as he entered another and ghastlier ward, was always the same: "I am true to my dynasty and I am thinking of my people." And this noble progress—surely as "royal" as any history records—he maintained from day to day till the panic was allayed and the disease was in full defervescence; and he returned to Rome—whence, by the way, though without his knowledge, his food and drink had been supplied—and encountered a reception as grandly impressive as ever fell to the lot of consul or emperor on the Sacred Way—alone, in a modest pony-carriage, without retinue, with difficulty making his way to the Quirinal through the dense masses of the population whose hearts were too full to cheer.

And this is the man whom Italy, who owes her unity and independence in great measure to his House, has just seen visited by the vendetta of a faction among her sons. True, it is more than probable that that faction is in collusion with the international organisation which is in perennial conflict with the prevailing social order and that this latest "example" for the "benefit" of crowned heads or constituted authorities is the result of a drawing by lot—which might have had for its object an even more conspicuous victim than King HUMBERT. But such complicity cannot absolve Italy from her pre-eminence as the instrument of such crimes—cannot blind the world to the fact that the pet, the spoiled child of modern liberalism, has made herself the recruiting sergeant of the political assassin—the source whence anarchy draws its most numerous, its most reckless, its most effective agents, whose deeds of blood have within the last four or five years been wrought on Frenchman, Spaniard, and Austrian alike—on victims absolutely unknown to their murderers, who had become the willing tools of a junto of conspirators sitting securely in congenial darkness. More than once—notably after LUCCHENI'S murder of the Empress ELIZABETH about two years ago at Geneva—THE LANCET has dwelt on the conditions, political and social, which give Italy her sinister priority in lethal crime. There is her "southern blood," all too imperfectly mitigated by education, by opportunities of honest bread-winning, by respect for the administration of justice. There is nearly half of her 30,000,000 of inhabitants almost wholly "analfabeti" (unlettered), starved not more physically than mentally; by temperament and by tradition peculiarly responsive to the sonorous rhetoric of the self-constituted vindicator of social wrong—himself again the product of Italy's bad educational and academic system, which multiplies the agitator at the expense of the artisan, the tradesman, even the husbandman. In his great scheme of university reform Dr. BACCELLI during his recent tenure of the portfolio of

Public Instruction pointed to the disastrous effects wrought on Italy by her 30 seats of learning granting degrees in many cases after the most superficial examinations, and inundating the country with unemployed professional men who, disdaining the prosaic life of the industrial bread-winner, find on the platform and in the press the channels through which their personality can make itself felt. "An academic proletariat." Such, in BACCELLI'S significant phrase, is the rank, unwholesome growth which is overrunning Italian public life; 500 "avvocati" and nearly as many "sanitari" and "ingegneri" in excess every year of the number that can make a modest livelihood out of these professions—a rapidly increasing force of the "hungry Greeklings" of Juvenal—"Graeculi" whose chosen career is that of "Gracchuli" or diminutive imitators of the heroes of Rome's præ-Sullan period. These glib orators and scribes are always in the political foreground, never more so than in Italy's latest general elections, the result of which was greatly to strengthen the socialist and anarchist vote and to intensify the feeling of discontent and unrest, with a corresponding belief in root-and-branch subversion of the prevailing order. We have no wish—it is certainly outside our province—to court political discussion; but, like every other public manifestation, politics are largely conditioned by forces physical and material, forces which in Italy have acquired a deteriorating power by neglect of laws in which all professions—none more than the medical—are interested. Bad economic and fiscal regulations, the tax on food, the enormous increase of adulteration, these and such like abuses coöperate with intellectual and moral anæmia to create a community well-nigh desperate with hardness of living and hopelessness of outlook. For the "academic proletariat" this is welcome, congenial soil to cultivate, and its products are the PASSANANTES, the CASERIOS, the ANGIOLLILLIS, the ACCIARITOS, the LUCCHENIS, and the BRESCIS, the ready instruments of the "International" who think that they are vindicating society and hastening the new heaven and the new earth of the socialist ideal. Italy has made several attempts to nip such products in the bud. She has organised a series of committees "Contro il Coltello" (against the knife); she convened a congress early in 1899 to counteract anarchists. Both proved abortive. Both were addressed to symptoms, not to disease at its source. It remains for her to effect economic, educational, and sanitary reforms, thorough and far-reaching, if she is to clear herself of the imputation of committing more homicides than all Europe (minus Spain and Portugal) put together and of crowning her priority in lethal crime by the assassination of a monarch of whom the world is already saying that she was not worthy.

THE letter from the honorary medical and surgical staff of the National Hospital for the Paralysed and Epileptic, Queen-square, which we print in another column gives an account of the differences which have arisen between the staff of this hospital and its board of management. These differences have now become so acute that the distribution committee of the Metropolitan Hospital Sunday Fund a few weeks ago recommended that the grant from the Hospital Sunday Fund should be withheld from the hospital until they are settled—a recommendation adopted by the council of the Fund a few days ago.

It is notorious that for some years the medical staff have experienced difficulties in communicating directly with the board and have more than once suggested as a means of obviating such difficulties that they should have representatives on the board. About a year ago, in consequence of the conditions under which matters affecting the staff were discussed by means of delegates to the board, the request for direct representation on the board was renewed. The staff, however, failed to convert the board to their view, and as a consequence were forced to address themselves to the governors of the hospital. This they did, urging weighty reasons for the granting of such representation and fortifying those reasons by describing a state of affairs at the hospital as regards diet, nursing, and administration generally by no means creditable to the institution. The board resented the fact that such charges were not first made to them, but considering the manner in which the board had received representations from the staff in the past and the apparent inefficacy of such appeals, the staff can scarcely be blamed for taking on the present occasion what promises to be a more effective way of dealing with abuses. It can scarcely be said that the means adopted by the board of investigating these charges were such as to command implicit confidence or carry much weight. They appointed a sub-committee of three from their own body, and abstained from invoking some independent and impartial authority which could have examined both the board and the medical staff. But even from the report of this sub-committee, read in the most favourable light, it is evident that a condition of affairs existed by no means creditable to the administration of the hospital and such as the board should have been acquainted with.

The board have recently issued to the governors a statement in reply to that of the medical staff embodying, amongst other things, the report of the sub-committee just alluded to, and purporting to give the reasons for their refusal to allow the staff any representation. To our readers it will appear strange that a medical staff, perhaps as a body the most widely known hospital staff in the world, should have even to ask for such representation; and we cannot help thinking that a board which refuses such a modest request is dangerously out of sympathy with medical requirements and culpably ignorant of the eminence and high position of the men whom it treats so cavalierly. But it is instructive to consider briefly the board's reason for refusal. Such representation, it is alleged, would endanger the independence of the board, whatever that may mean. It does not seem to occur to the board that the medical staff whose names are so closely identified with the hospital have at least an equal interest with members of the board in maintaining the efficiency and enhancing the reputation of the hospital. It is also alleged that with two medical representatives on its board of management the hospital would be "in danger of having the philanthropic aspect of its work subordinated to that which is merely scientific and investigatory." We cannot help asking whether such a statement is really made seriously by a body of

men controlling a large hospital and presumably at least slightly acquainted with hospital matters? Are we to assume that every hospital in London with two or more medical members on its board of management—and this means a great majority of London hospitals—has the "philanthropic aspect of its work subordinated to that which is merely scientific and investigatory"? The childishness of such a statement alone saves it from being libellous, and we doubt whether it will carry weight even amongst the prejudiced and bigoted few for whom apparently it is meant. It is evident that under the special circumstances this question of representation is one of the highest importance. We shall return to this subject, but in the meantime it is to be hoped that the matter will be referred to some independent but competent body, in order that a grave danger may be averted from an institution which not only in England but throughout Europe and America has become, in virtue of its medical and surgical staff, identified with the most advanced neurological science, the most effective therapeutics, and the highest teaching.

WE would call our readers' attention to two recent publications which have important bearings upon the subject of the deplorable amount of enteric fever that has been prevalent among our troops in South Africa. The first is the correspondence, which has been issued as a Parliamentary paper, between Sir WALTER FOSTER, M.P., and Mr. WYNDHAM, M.P.; the second is an article by Mr. SAMUEL OSBORN, F.R.C.S., on "A Sanitary Corps for the British Army," published in the *Journal of Tropical Medicine* for July. The subject is one of immense importance seeing that it deals with the sanitary precautions which should be undertaken in future wars and as to how and on what scale they should be organised and adopted in order to be efficient. We cannot do better than take these publications as the text for a few observations, it being understood, however, that the matter is of such proportions that it cannot be at all exhaustively treated and threshed out within the limits of a short article. Army hygiene is but the application of the laws of health to the varying conditions of war. The conditions may be inflexible or the reverse, but they will rarely be so elastic and advantageously modifiable under the circumstances of war as under those of ordinary life. Where an enemy, for example, has captured the waterworks of a place or fouled the sources of supply and the troops are compelled to have recourse to a contaminated water-supply the mischief is soon done and it is irretrievable. Writing on Oct. 31st of last year Sir WALTER FOSTER pointed out that "in all human probability there will be great loss of life from fever and other maladies more or less preventable by careful sanitary work," and suggested the sending out of a small sanitary commission or a commissioner with assistants. Sir WALTER FOSTER placed his services at the disposal of the War Office, offering to go out in an unpaid capacity. Mr. WYNDHAM, after having consulted Lord LANSDOWNE and the medical authorities at the War Office, thought that the "need of special assistance is not the same in sanitary matters as in surgical operations." The Director-General and Lord LANSDOWNE therefore did not see the necessity for a commission such as was suggested. Mr. WYNDHAM consequently declined, with thanks, Sir WALTER FOSTER'S offer of service.

We fully recognise the patriotic spirit which animated Sir WALTER FOSTER in making this offer. Let us consider his suggestion in its practical bearings and assume by way of argument that, in addition to the presence of Sir WALTER FOSTER on the small sanitary commission, he was aided by some of the ablest and best sanitary authorities and that their advice and recommendations were of the wisest and soundest. Still, having regard to the immense area covered by the theatre of war in South Africa, it seems to us that there would be no guarantee that the sanitary commission, unless it were ubiquitous, would have been present when and where its recommendations were most needed; we do not see how their recommendations could have been carried out except through the instrumentality of a large sanitary executive body, or how this body could have got to work until a place had been captured. Moreover, it is difficult to understand what a commission could have effected practically where a large advancing force had outmarched its supplies and the amount of available transport was altogether inadequate to its requirements. Under such circumstances the military authorities would obviously have been powerless for the time being to have given effect to the recommendations of any small sanitary commission. It must be admitted that it occasionally happens in war that the military requirements override all other considerations and that this could only be prevented or overcome by getting the enemy to forbear fighting until his opponents were ready. The fighting material has to be present first in order to capture and hold a position and protect any non-combatant labour in the execution of any necessary sanitary work.

The proposals contained in Mr. OSBORN'S paper are, it strikes us, of a much more practical character seeing that he advocates the formation of a "*corps sanitaire*" in the British army like those found in continental armies. This is no new idea. It will be remembered that in effect this question was a good deal discussed in the report of the Army Hospital Services Inquiry Committee after the Egyptian expedition of 1882, and that General Sir JOHN ADYE (who was Chief of the Staff in that war), Sir JAMES HANBURY (who was the principal medical officer), and others gave evidence bearing on this subject. It is a question, however, of much greater difficulty than is commonly supposed. It is often not practicable to employ unarmed civilian labourers on just effecting a landing on an enemy's soil or soon after attacking and capturing an enemy's position. The trend of military opinion seems to be against the increase of non-combatant establishments so as to overweigh the real fighting element and lessen the mobility of the army; the very restricted sphere of labour of a sanitary executive in any campaign, where rapidly executed movements are made, has to be taken into account, although the great utility of such an organisation in the case of sieges or where what may be termed sedentary camps and armies are concerned, and when time is not a pressing element, is fully recognised. In war we usually find that the staff of an army is overwhelmed with work and responsibility, that

transport is *the* difficulty in almost every campaign, and that the question is not so much as to what it is necessary or expedient to do but as to the means of getting it done and that with sufficient promptitude to be efficacious. For our own part, while recognising the force of the reasons that may be urged from a purely military point of view, we hold that there should be with any army in the field, in addition to the officers of the Royal Army Medical Corps, who are not only specially trained in army hygiene but should be fully alive to its great practical importance on field service, some sanitary officers of practical experience, specially selected and told off for that particular purpose, and that there should also be a large and well-organised body for executive sanitary work, such as conservancy and disinfection. It must be a large body to be of any good in a big campaign and possess a staff of directing officials practically acquainted with sanitary work. This might possibly be formed in connexion with the Quartermaster-General's Department, but it should be under the orders and at the disposal of those charged with, and directly responsible for, advising on all matters of army hygiene. Moreover, we have always held that one of the weak points of our present field medical service administration is transport. The medical service should have an independent transport entirely at its disposal which ought not to be diverted to any other purpose, except, as we have previously said, in cases of grave emergency and under the express order of the general in command who should, of course, be prepared to justify his action. These are matters which may most usefully occupy the attention of the South African Commission in the course of its inquiry and may possibly lead to some practical suggestions being made.

THE Centenary Festival of the Royal College of Surgeons of England, which commenced on Wednesday, July 25th, was concluded on Friday evening, July 27th, the final entertainment being a conversazione given at the Mansion House by the Lord Mayor of London. We gave last week some notes of the earlier proceedings and published an abstract of the Address of Welcome by the President; we now conclude our account of the Festival with reports of the meeting held at Burlington Gardens on Thursday afternoon, July 26th, when the Honorary Fellowships were bestowed, and of the Centenary Dinner held on the evening of the same day at Lincoln's Inn Hall (vide p. 339). Each of these meetings may without exaggeration be described as a brilliant success, and the President and Council must feel gratified that their strenuous endeavours fittingly to commemorate the Centenary of the College have by no means been in vain. That the PRINCE OF WALES has received a "qualification" in Surgery to add to that which he already possessed in Medicine is a fact which will be hailed with acclamation by every member of our profession, and it is, we think, a step in the right direction that is taken when leaders of the State such as the Marquis of SALISBURY and the Earl of ROSEBERY are attached to us, lightly though it be, by the link of an Honorary Fellowship. The outside world would perhaps learn to understand and appreciate us better if the calls of our daily duties left us leisure to mingle with them more freely than we do. The gathering at Burlington-gardens was a most remarkable one—noteworthy not only for its brilliance as a ceremonial but for the tribute paid to British surgery as represented by the Royal College of Surgeons of England by most distinguished foreign surgeons from all parts of the world, representative men occupying the highest professional positions in their respective countries, who showed their appreciation of the honour offered to them by travelling long distances to accept it, for it was laid down as essential that he to whom the Honorary Fellowship was offered should on this occasion be present to receive it *in propriâ personâ*. This is, we think, emphatic testimony of the estimation in which British surgery in general, and the Royal College of Surgeons of England in particular, are held. We are glad to know that our *confrères* from abroad were impressed and pleased with their reception; that they valued the distinction which was bestowed upon them is, as we have already said, evident by their acceptance of it. Our readers will find in another column the graceful words of appreciation in which certain of them expressed their thanks to the College.

Annotations.

"Ne quid nimis."

THE LATE DUKE OF SAXE-COBURG AND GOTHA.

THE death of the Duke of Saxe-Coburg and Gotha, more familiarly known in England under his title of Duke of Edinburgh, though sudden at the end was not unexpected, for he was smitten with a mortal disease. The late Prince, a reserved and quiet man, was an excellent practical sailor and rose to a very high grade in the navy. It must have been a considerable wrench to him to leave his place in English society to become a German ruler, but having decided to carry out the trust extended to him he finished his life as a loyal supporter of his nephew the Emperor William and of United Germany. His only son having died under sad circumstances and the Duke of Connaught having waived for himself and his family the succession to the dukedom, the Duke of Albany becomes reigning Duke of Saxe-Coburg and Gotha.

EPSOM COLLEGE.

"FOUNDER'S DAY" took place on Saturday, July 28th, when a large company assembled to assist at the distribution of prizes in the big schoolroom of the College. The headmaster, the Rev. T. N. Hart-Smith, M.A., was able to make a very satisfactory announcement as to the general state of the College and the progress of the boys; to give one instance, he said that two whole forms, without any selection whatever, were sent up for the London Matriculation, and that of these 20 boys 16 passed. He also referred to various honours that had been won by old Epsomians. As has already been stated in our columns,[1] the "Wakley Prize," which was established as a memorial of the Founder of THE LANCET, and which is awarded biennially by the votes of his schoolfellows and the approval of his masters to the most popular boy, was gained by an unusually large majority by Colin Giffard (a son of Mr. D. W. Giffard, M.R.C.S., of Brighton), to whom the eldest grandson of Thomas Wakley had the pleasure of presenting it. Dr. Propert, in presenting the

[1] THE LANCET, June 23rd, p. 1816.

"Propert Prize" for the highest honour won during the year to C. Lawton, alluded all too briefly to the splendid work of his father, the Founder of the College, and Sir Joseph Fayrer, the chairman, in presenting the "Martin" Prizes for classics and mathematics took occasion to insist on the value of a preliminary classical education not only for medical but for all other studies. After the distribution of prizes the company adjourned to the beautiful grounds of the College, which, refreshed by the welcome rain of the preceding day, were seen to the best advantage. An organ recital given in the chapel by the organist, the Rev. Dr. Rowton, concluded the proceedings. The boys seemed well and happy, and the College, which is, if we may use such a phrase in the columns of THE LANCET, not *too* (i.e., exclusively) medical, is certainly doing excellent work. So, to borrow a sentiment from Westminster and Eton, we say "Floreat."

THE EARLIEST SIGNS OF TUBERCULOSIS.

PROFESSOR BOZZALO of Turin in a paper read at the recent International Congress of Tuberculosis at Naples has conveniently summarised the following 11 important points which are of assistance in forming a diagnosis of pulmonary phthisis in its earliest stages. They are as follows:—1. Albuminuria alternating with phosphaturia. 2. A pseudo-chlorosis distinguishable from true chlorosis by the slighter degree of reduction of the hæmoglobin and by the less-marked vascular and cardiac disturbances (palpitation, soft pulse, pulsating arteries, &c.). 3. The presence of gastric disturbances like gastralgia, anorexia, nausea, and vomiting. 4. Tachycardia in the absence of fever. 5. Diminution of blood-pressure. 6. A rise of temperature following bodily or mental exertion above the slight rise proper to health. In women a rise of from 0·3° to 0·4° C. is observable before the onset of each menstrual period. 7. An undue tendency to sweat after exertion, mental or bodily; also night sweats. 8. Pain in the supra-orbital regions and in the neck. 9. A slight inequality of the pupils with a tendency to dilatation (mydriasis). 10. The occurrence of herpes zoster. 11. Enlargement of the spleen. Of these the first seven symptoms are the most frequently met with and possess considerable diagnostic value.

AGORAPHOBIA AND HYPNOTIC SUGGESTION.

IN the *Edinburgh Medical Journal* for July Dr. C. Lloyd Tuckey has published two interesting cases of agoraphobia treated by hypnotic suggestion. They are as follows:—Case 1. A young lady, aged 26 years, who was strong and healthy and of robust physique, had noticed for about two years that she felt nervous in church and uncomfortable in shops. This feeling increased until she became unable to enter any crowded building and very averse to going out alone. Her family history showed a freedom from mental disease and she had personally never had a serious illness. She was not on good terms with the head master of her school and this preyed on her mind, but otherwise she had no trouble. She consulted her medical man who prescribed bromides and tonics and ordered rest from work. These measures not being successful and the symptoms growing steadily worse she was subjected to hypnotic treatment. The Nancy method of hypnotising was adopted, she passed into the somnambulic stage at the second sitting, and suggestions were then made to combat her morbid fears. She was strongly assured that she would gain confidence and be able to go about as before and attend church on Sundays. She began to show improvement after this, and on the following Sunday of her own accord she expressed a wish to attend a short children's service at a neighbouring church. "She did this without discomfort, and during the following week went to concerts and theatres without fear." She was also able now to go out shopping, and after two weeks' treatment returned to her school-work and continues well. The symptoms (constituting agoraphobia) which she had experienced before when in a crowded building—such as faintness, giddiness, palpitation of the heart, and a stifling sensation at the chest, with a vague terror which she could not control—have disappeared. Case 2 was that of a man, aged 37 years, strong, healthy-looking, married, and with a family. He led a healthy life and was a first-rate golfer. He had influenza badly in October, 1899, but made a good recovery. He was perfectly well, he said, except for his "nerves," and he felt thoroughly ashamed and disquieted at their condition. He was unable to go about alone and had to be accompanied to and from his office. "He could not enter a church or theatre without feeling such depression and terror that he was forced to retire." The symptoms were beginning to affect his spirits and to keep him awake at night so that his health was failing. Under the influence of hypnotism he passed into the cataleptic stage and was very susceptible to suggestion. He was assured that he would gradually regain self-confidence and self-control, and that in a week's time he would be able to go to a theatre without discomfort. He was hypnotised daily for a week and twice afterwards. On the day named he attended a matinée performance at a theatre without difficulty. He has since resumed his ordinary life and is completely cured. At golf he was as good before as during his illness, his morbid symptoms and troubles (nervousness and feeling of fear) only occurring while in enclosed places or amidst crowds. Dr. Tuckey points out the value of hypnotic treatment in this class of case. Both agoraphobia and its opposite, claustrophobia, are favourably influenced by hypnotic suggestion if the patient is at all hypnotisable. He, however, records two instances where the patients failed to be hypnotised, though every method he could think of was tried.

GANGRENE FROM THE APPLICATION OF DILUTE SOLUTIONS OF CARBOLIC ACID.

THE *American Journal of the Medical Sciences* for July contains a very complete and important paper on this subject by Dr. F. B. Harrington. In the United States carbolic acid has become a general household remedy for the treatment of slight wounds and bruises and it is used as a moist dressing. The application of dilute carbolic acid for hours to the extremities may produce gangrene—a fact which is not generally known. Dr. Harrington has seen during the last five years at the Massachusetts General Hospital, either in his own practice or in that of other surgeons, no less than 13 cases of gangrene arising from the use of carbolic acid. From medical literature he has collected a large number of other cases which with his own make 132. The recorded cases appear to be entirely American and continental. The absence of British cases is no doubt due to the fact that a dilute solution of carbolic acid applied in the form of a moist dressing is not a household remedy in this country. However, the possibility of carbolic acid being used in this manner is by no means remote, so that the warning given by these cases is not useless. Dr. Harrington relates the following case. A delicate woman, aged 26 years, cut the tip of her right index finger. Her brother, a strong man, had two weeks before successfully treated a cut on his finger with a solution of carbolic acid. She therefore put on a bandage saturated with the same solution. This was at 6 P.M. On going to bed she moistened the dressing again with the solution. There was some pain in the finger during the night. In the morning when the dressing was removed the skin was grey and the finger was swollen and felt "lifeless and heavy." The colour changed in a few hours to a dark brown and later,

when the finger became dry, to black. The patient was first seen at the end of four weeks. The finger was in different places clay-coloured, dark brown, and black. A line of demarcation had formed near the end of the first phalanx. The remainder of the phalanx was red and swollen. Amputation was performed through the middle. Thrombosis of the vessels, superficial necrosis of the finger, and deeper purulent infiltration and hæmorrhage were found. The history of all the cases is similar. After an injury a finger or a toe is wrapped in a dressing saturated with carbolic solution. If the solution is strong enough and the time of application is sufficiently long the part will be lost. Numerous cases have been reported in which amputation had to be performed for gangrene following the use of 2 per cent. and 3 per cent. carbolic solutions. In a child, aged 10 years, the second and third phalanges of a finger were lost after the application of a 1 per cent. solution for 24 hours. Usually the time of application was from 12 to 24 hours. By a series of experiments Lévai has shown that the gangrene is due to a direct chemical action of the carbolic acid on the tissues and that other dilute chemicals have a similar effect. Five per cent. solutions of muriatic, nitric, sulphuric, and acetic acids, and of caustic potash, produced gangrene when applied to an extremity for from 20 to 24 hours. On the trunk superficial gangrene occurs if the application is sufficiently prolonged. The result is not so injurious as on the extremities because of the greater thickness of the tissues and because the blood supply cannot be shut off in the same manner as in an extremity.

THE USE OF STERILISED MILK.

QUESTIONS are from time to time raised as to how far the use of sterilised milk for the feeding of infants may be desirable in the interests of the public health, and there are those who allege that sundry infantile diseases are accentuated by the exhibition of milk thus prepared. Although some of the considerations upon which objections to this sterilisation of milk are based are somewhat theoretical in nature it is important that all experiments in this direction shall be closely watched. The subject is one of no little importance to the public health, and more especially at a time like the present, when there is considerable difficulty—at any rate without the use of preservatives of one or another description—in supplying fresh milk. Under these circumstances the progress of the Infant Milk Depôt at St. Helens is not without interest. The health committee of that borough has taken seriously to heart the raid which death makes yearly in its infantile population, and it determined to study by means of a sub-committee the work which is being done in England and in France in the direction of "sterilised humanised milk." In London it was found that considerable progress was being made and that a large portion of the public were quite willing to pay the small extra charge which is being made for such milk. At Fécamp in Normandy it is claimed that the infantile mortality has been reduced from 243 to 140 per 1000 births by the use of this milk which is sterilised and humanised under medical supervision. The bottles, which are arranged in sets of nine are, after being sterilised, placed upon numbered shelves, the numbers corresponding to the number of the child for whom the bottles are intended. The parent calls for the bottles and replaces on the shelf the empty nine bottles which were taken the previous day. The nine bottles represent nine feeds per day in such quantities as the age of the babe necessitates, the children being brought weekly for inspection and weighing. At Havre there is a similar society at work. The movement is essentially philanthropic in character but the municipal authorities have been so impressed with its work that they are about to subscribe to the funds of the society. The St. Helens sub-committee were evidently edified by the results attained and they consequently recommended the town council to inaugurate a similar system in St. Helens. In August, 1899, a depôt was opened much on the Fécamp lines and by the end of the month 80 children were being daily fed from it. In consequence of the praiseworthy and public-spirited efforts of the council in this sense there has, Dr. Drew Harris, the medical officer of health, reports, been a great reduction in the infantile mortality of the borough. A large number of children already suffering from diarrhœa were brought to the depôt during August and September, a remarkable improvement having in many cases resulted. Dr. Harris speaks hopefully of the venture and all those working for the reduction of infantile mortality will watch the progress of the scheme with much interest.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

THE Society for the Study of Disease in Children was inaugurated at a meeting held on July 24th at the rooms of the Royal Medical and Chirurgical Society in Hanover-square. The chair was taken by Dr. A. E. Sansom. There was a fair attendance of those interested in the movement. The rules, as drafted by the provisional committee, were adopted with some slight alterations. The officers and council of the new society are as follows. Honorary treasurer: Mr. Clement Lucas (London). Council: Mr. H. G. Armstrong (Wellington College), Dr. Henry Ashby (Manchester), Dr. Fletcher Beach (London), Dr. George Carpenter (London), Dr. Edmund Cautley (London), Dr. Wayland C. Chaffey (Brighton), Dr. Arthur Downes (Local Government Board), Mr. Walter Edmunds (London), Dr. Theodore Fisher (Bristol), Dr. Leonard Guthrie (London), Mr. Robert Jones (Liverpool), Dr. David B. Lees (London), Dr. Lewis Marshall (Nottingham), Dr. John McCaw (Belfast), Mr. D'Arcy Power (London), Dr. Humphry D. Rolleston (London), Dr. A. E. Sansom (London), Dr. George E. Shuttleworth (Richmond), Mr. Harold J. Stiles (Edinburgh), Dr. George A. Sutherland (London), Dr. James Taylor (London), Mr. Alfred H. Tubby (London), Mr. William H. Vickery (Newcastle-on-Tyne), and Dr. Dawson Williams (London). Honorary secretaries: Mr. Sydney Stephenson (London) and Dr. Charles H. Willey (Provincial). The society already numbers upwards of 80 original members.

PREPUTIAL CALCULI.

IN the *Boston Medical and Surgical Journal* of June 21st Dr. A. N. Blodgett has described a case of this very rare condition. The patient was a man, aged 22 years, who was of neurotic antecedents and at puberty had been in an asylum for *folie de doute*. He recovered in a few months and since that time had been engaged in business. There was extreme phimosis of a greatly elongated prepuce. No part of the glans could be exposed. The penis as a whole was small, but the distal portion was greatly enlarged, elongated, and pendulous, presenting somewhat the appearance of a small pear over which the prepuce was tightly extended. The orifice was directed to one side. On micturition the stream was discharged at an angle to the penis. The swelling was very hard, unyielding, and tender. A greenish, purulent, ammoniacal, and offensive discharge constantly issued from the orifice which was excoriated and painful. The effect on the patient was most depressing and mental symptoms similar to those which he had suffered from before were being induced. The prepuce was laid open on a director, disclosing a perfect calcareous collar around the base of the glans, filling the sulcus and prolonged upon the glans towards the meatus. The collar was broken in removal. A portion of the redundant prepuce was removed and the flaps were sutured.

Healing was uneventful. Dr. Blodgett refers to another case published in *La Grèce Médicale*, No. 7, 1899, by Dr. A. Louis of Velessa, Macedonia. The patient was a man, aged 45 years, the father of three children, who from feelings of modesty concealed his condition for seven years until he was forced to seek advice. At first pain was slight, but later it increased. The penis resembled in shape the pendulum of a clock. The prepuce was of the form of a pear and was 25 centimetres in circumference and felt like a bag full of sand. From the preputial orifice a muco-purulent, fœtid, and ammoniacal fluid constantly flowed. On incision 110 calculi and some sandy detritus were removed. 30 of the calculi reached the size of a pea, the others diminished to that of a grape seed. During the whole period, except towards the end, when the pain became too great, coitus was performed. It is to be regretted that an analysis of the calculi was not made apparently in either case.

THE STANDARDISING OF DRUGS.

THE Secretary of State for the Home Department a short time ago requested the Royal College of Physicians of London and the Royal College of Surgeons of England to advise him in reference to an application from a firm of manufacturing chemists for the performance at their laboratories of experiments on living animals for the purpose of standardising drugs. Three questions were submitted for answer, and the matter was referred to the Laboratories Committee of the Colleges for consideration and report. The Committee have issued a report answering the questions above referred to. The first was: "Is the standardising of drugs by means of experiments on animals indispensable in the public interest?" The reply is to the effect that the standardising of some remedies is a chemical process and does not involve experiments upon animals. With certain other remedies, however, containing active agents which cannot be estimated by any known chemical process, experiments on animals are absolutely necessary in order that the therapeutical strength of the drugs may be estimated. This applies more particularly to the groups of remedial agents, antisera, which have been introduced for the treatment of infective disease. An unstandardised antitoxin is, of course, a source of danger. The second question ran thus: "If so, is it desirable that, in proper cases, duly qualified experimenters working in the premises of manufacturing chemists should be empowered to perform the necessary experiments on animals for this purpose?" The reply of the Committee is a decided negative. The members "regard the authorisation of the necessary experiments in the premises of manufacturing chemists as highly undesirable." The arguments adduced in favour of this view are sound and clearly expressed, but we have not space to state them in detail. The last question for consideration was: "If it is not thought desirable that manufacturing chemists should be entrusted with this power, what other provision is it advisable and practicable to make for the purpose?" The reply to this could not have been easy to formulate but we believe the suggestions of the Committee will meet with the approval of all medical men and of those who are interested in the health of the community at large and unbiased by the sentimental objections put forward by the anti-vivisectionists. While the Committee think that it is undesirable for a licence to be given to any firm of manufacturing chemists they are strongly of opinion that it is essential for the public welfare that in the case of the antisera the antitoxic strength of the remedies should be tested and certified by some responsible authority. They suggest that the standardisation might be carried out either by the Government directly in a State laboratory or by some public body or bodies with the sanction of the Government. In Germany the standardisation is carried out in a State laboratory under the direction of a Minister; in France it is undertaken by the Pasteur Institute; while in New York the State is responsible for the work. Reference is then made to the excellent work undertaken by the Royal College of Physicians of London and the Royal College of Surgeons of England in the public interest and without pecuniary advantage. It is to be hoped that the Home Secretary will act upon the suggestions of the Committee, the weight of whose authority is unquestionable, and that laboratories will be authorised for the standardisation of the antisera.

IN our last issue, p. 242, we published the presidential address delivered at the British Pharmaceutical Conference by Mr. E. M. Holmes who was inadvertently described as President of the Pharmaceutical Society. Mr. Holmes is President of the British Pharmaceutical Conference, the President of the Pharmaceutical Society for the current year being Mr. G. W. T. Newsholme.

A TELEGRAM has been received at the Colonial Office from Sir H. A. Blake, the Governor of Hong-Kong, dated July 30th, and recording 33 cases of bubonic plague with 34 deaths during the last week.

THE Library of the Royal Medical and Chirurgical Society is now closed for cleaning, &c., and will be re-opened on Monday, Sept. 3rd, at 11 A.M.

THE THIRTEENTH INTERNATIONAL MEDICAL CONGRESS AT PARIS, AUGUST, 1900.

(BY TELEGRAM.)

THE Thirteenth International Medical Congress was opened yesterday (Thursday) in Paris. President LOUBET received the international delegates in the morning at the Elysée and M. Monis, Minister of Justice, presided at the first general meeting in La Salle des Fêtes. Professor LANNELONGUE, President of the Congress, thanked M. Monis for his welcome to the Congress, and in his address suggested the adoption of a universal nomenclature for, and a natural classification of, morbid phenomena. Over 1200 communications have been received from contributors to the proceedings of the Congress. Upwards of 5000 medical men have registered as members of the Congress, 757 being Russian, 554 German, 369 American, 316 Italian, 217 British, and the rest for the most part French.

POISONING BY BENZOLINE.—Mr. S. Craddock held an inquest at Burnham, Somerset, on July 23rd upon a little boy who had swallowed some ounces of benzoline instead of water. The child became unconscious and died within 30 minutes. A verdict to the effect that death was caused by drinking benzoline in mistake for water was returned.

ACTION AGAINST A WATER COMPANY.—At the Swansea County-court on July 25th a barrister summoned the Oystermouth Waterworks Company for neglecting to supply him with water for domestic use at his house, Caehir, Westcross. The magistrates imposed a penalty of £10 and £2 for every day since July 18th on which water had not been supplied.

PUBLIC BATHS AT ISLINGTON.—The Islington Vestry and Sanitary Authority have just completed extensive additions to the public baths in the Hornsey-road. There are now provided a new first-class swimming bath for women, 37 additional private baths, and a new laundry, with necessary accessories thereto. The total outlay of these additions is estimated at about £61,000.

THE CENTENARY FESTIVAL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

(*Continued from p. 284.*)

ADMISSION OF HONORARY FELLOWS.

AS we briefly announced last week the centenary meeting was held in the theatre lately used by the University of London at Burlington-gardens on Thursday afternoon, July 26th. The President, Sir WILLIAM MAC CORMAC, having delivered an Address of Welcome (*vide* THE LANCET, July 28th, 1900, p. 281), the following Honorary Fellows who had been elected on the previous day were admitted:—

ALBERT, EDUARD, M.D., Professor of Clinical Surgery, University of Vienna; Member of the Austrian House of Lords and of the Supreme Sanitary Council; Royal Imperial Councillor of State.

BALL, CHARLES BENT M.D., M.Ch., Regius Professor of Surgery, University of Dublin; Surgeon to Sir Patrick Dun's Hospital; Consulting Surgeon to Steevens' Hospital, Dublin.

BASSINI, EDOARDO, M.D., Professor of Clinical Surgery, Royal University of Padua; Commander of the Order of the Corona d'Italia.

BENNETT, EDWARD HALLARAN, M.D., M.Ch., Professor of Surgery, Trinity College, Dublin; President of the Royal Academy of Medicine in Ireland.

BERG, JOHN WILHELM, M.D., Professor of Surgery, Royal Caroline Institute of Medicine and Surgery, Stockholm; Surgeon to the Royal Seraphim Hospital; Member of the Direction of the "Sophiahouse"; Member and Ex-President of the Swedish Medical Society and of the Scandinavian Surgical Association.

VON BERGMANN, S. Exc. Professor Dr. ERNST, Geh. Med. Rath; Royal Prussian Medical Privy Councillor, Imperial Russian Actual Councillor of State, Knight of the Prussian Order of Hohenzollern, the Prussian Kron and Red Eagle Orders; Knight Grand Cross (with Diamonds) Imperial Russian Orders of the Holy Anne, of the Holy Stanislas and the Holy Vladimir. General-Arzt of the Prussian Army with the rank of Major-General. Served in the Franco-German and Russo-Turkish Wars.

BLOCH OSCAR THORVALD, M.D., Professor of Clinical Surgery, University of Copenhagen; Physician in Ordinary to His Royal Highness the Crown Prince of Denmark; Surgeon to the Royal Frederiks Hospital; Member of the Royal Board of Health of Denmark.

CAMERON, IRVING HEWARD, M.B., Professor of Surgery and Clinical Surgery, University of Toronto; Surgeon to the Toronto General Hospital.

CARDENAL FERNANDEZ, SALVADOR, M.D., Vice-President of the Royal Academy of Medicine and Surgery of Barcelona; Director of the "Hospital del Sagrado Corazon" of Barcelona; Commander of the Royal Order of Isabella the Catholic.

D'ANTONA, ANTONINO, M.D., Professor of Surgery, Royal University of Naples; Professor of the Propedeutica Chirurgicale, and of the Institute of Surgical Pathology, of Naples.

DURANTE, FRANCESCO, M.D., Senator; Professor of Clinical Surgery, Royal University of Rome; President of the Royal Medical Academy of Rome; President of the Italian Surgical Society; Knight of the Most Distinguished Order of the "Merito Civile di Savoia"; Knight Grand Cross of the "Corona d'Italia."

HALSTED, WILLIAM STEWART, M.D., Professor of Surgery, Johns Hopkins University, and Surgeon to the Johns Hopkins Hospital, Baltimore.

INGSTON, Hon. Sir WILLIAM HALES, M.D., LL.D., D.C.L., Professor of Clinical Surgery, Laval University, Surgeon-in-Chief, Hotel Dieu Hospital, Montreal; Senator of the Dominion of Canada.

MESON, Surgeon-General JAMES, C.B., M.D., LL.D., Director-General, Army Medical Service; Knight of Grace of the Order of St. John of Jerusalem in England. Served in Canada, West Indies, and Egypt, and in the Franco-German War.

KEEN, WILLIAM WILLIAMS, M.D., LL.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia; President, American Medical Association; President, College of Physicians of Philadelphia.

KOCHER, THEODOR, M.D., Professor of Clinical Surgery, University of Bern; Colonel, Medical Department of the Swiss Federal Army; President of the Swiss Medical Association.

KÖNIG, FRANZ, M.D., Geh. Med. Rath; Professor of Surgery; Director of Clinical Surgery at the Charité Hospital, Berlin; General-Arzt à la suite of the Army Medical Corps. Served in the Franco-German War as Consulting Surgeon to the Prussian Army.

KÜSTER, ERNST GEORG FERDINAND, M.D., Geh. Med. Rath; Professor of Surgery and Director of Clinical Surgery, Marburg; General-Arzt of I. Class à la suite of the Medical Service of the German Army.

LAMBOTTE, ELIE D. H., M.D., Surgeon of the Hospital "Bon Pasteur," Bruxelles; Professor at the "Institut des Hautes Études."

LANNELONGUE, ODILON MARC, M.D., Professor of Surgical Pathology, Faculty of Medicine, Paris; Member of the Academy of Medicine; Member of the Academy of Sciences; Surgeon, "Hôpital des Enfants Malades."

LENNANDER, KARL GUSTAF, M.D., Professor of Surgery and Obstetrics, University of Upsala.

MACEWEN, WILLIAM, M.D., LL.D., F.R.S., Regius Professor of Surgery, University of Glasgow.

MACLEOD, Colonel KENNETH, M.D., LL.D., Indian Medical Service; Professor of Clinical and Military Medicine, Army Medical School, Netley; late Professor of Anatomy and Clinical Surgery and of Systematic Surgery, Calcutta Medical College.

NICOLAYSEN, JULIUS, M.D., Professor of Surgery, Royal University of Christiania.

NORBURY, Sir HENRY FREDERICK, K.C.B., Director-General, Medical Department of the Royal Navy. Served in the Kaffir and Zulu Wars, 1878 and 1879.

OLLIER, LÉOPOLD, M.D., Professor of Clinical Surgery, University of Lyons.

PACHOUTINE, VICTOR, M.D., Privy Councillor; President and Professor, Imperial Military Academy of Medicine, St. Petersburg; President, Medical Council of the Empire; Knight of the Orders of St. Stanislas, St. Anne, St. Vladimir, and Prince Daniel.

POZZI, SAMUEL, M.D., Professor, Faculty of Medicine of Paris; Surgeon, Hôpital Bichat.

RAYE, Colonel DANIEL CHARLES O'CONNELL, M.D., Indian Medical Service; late Professor of Surgery, Calcutta Medical College, and Senior Surgeon, Calcutta General Hospital.

RODDICK, THOMAS GEORGE, M.D., LL.D., Professor of Surgery, McGill University, Montreal; Consulting Surgeon, Montreal General Hospital and Royal Victoria Hospital, Montreal; Member of the Canadian Parliament; Hon. Surgeon to His Excellency the Governor-General of Canada.

RUBIO Y GALI, FEDERICO, M.D., Medical Councillor; Member of the Royal Academy of Medicine of Madrid; Founder of the Hospital and Surgical Institute, Madrid.

TILLAUX, PAUL, M.D., Professor of Clinical Surgery, Faculty of Medicine, Paris; Member of the Academy of Medicine; Surgeon of the "Hôpital de la Charité."

WARREN, JOHN COLLINS, M.D., LL.D., Professor of Surgery, Harvard University; Surgeon, Massachusetts General Hospital.

WEIR, ROBERT FULTON, M.D., Professor of Surgery, College of Physicians and Surgeons, Columbia University, New York; Surgeon, New York Hospital and Roosevelt Hospital; President, American Surgical Association.

After the admission certain of the Honorary Fellows made speeches on their own behalf and that of their colleagues:—

Professor E. VON BERGMANN. (*Translation from German.*)

MR. PRESIDENT,—I beg to be allowed to thank you in the language of my country for the high distinction which has just been conferred upon us, the German-speaking surgeons.

The language of one's native land comes direct from the heart, and it is in the language of our mother that we address our dearest on earth. The German-speaking surgeons have always sought their dearest and most cherished model in the constitution, organisation and achievements of the Royal College of Surgeons of England.

Just as John Hunter by his own power founded the greatest and most beautiful anatomical and surgical museum, so have also his successors independently and relying on their own resources understood how to increase their rich inheritance in a wonderful manner, to accomplish great things brilliantly, and always to march with the times.

To be received by *such* men, into *such* a fellowship, is an honour than which no higher can be conceived.

We all wish to express to you, Mr. President, our warmest and most cordial thanks.

Professor DURANTE. (*Translation from Italian.*)

In the name of my Italian colleagues and my own I thank you, Mr. President and the illustrious College which has invited us to this memorable festival.

Our gratitude for the high honour which you have deigned to confer upon us this day is as deep as the traditions of the Royal College of Surgeons of England are able and as profound as its merits in the progress of science and the surgical art are great.

From this temple consecrated to science, of which the priests are always brothers and devoid of all unwholesome political bias, may I be allowed to proffer a respectful salutation to glorious and mighty Britain?

Dr. W. W. KEEN.

MR. PRESIDENT, MY LORDS, LADIES, AND GENTLEMEN,—On behalf of my American colleagues and myself it gives me great pleasure to return our very hearty thanks for the honour just conferred upon us. We regard it as the highest surgical honour we could receive, for "Praise from Sir Hubert is praise indeed."

Though the Royal College of Surgeons of England has attained a venerable age, it is far from decrepitude. No better evidence of this could be found than the many Members and Fellows who at the call of duty so cheerfully went to the front in South Africa. Foremost among them was your distinguished President, who, though he has reached an age when most men seek repose and slippered ease, responded to his country's call with his customary energy and alacrity. Happily the war is now nearing its end. Apart from any political results in South Africa it has had two results in which we may well rejoice. It has bound together Great Britain and her colonies in one solid empire; and through the wise statesmanship of the Most Noble Marquis of Salisbury and His Excellency the American Ambassador has joined Great Britain and America in a firm moral union in which Her Majesty if not monarch of our persons is surely queen of our hearts.

We come to you as representatives of four of our great institutions of learning—from Harvard, heavy with the snows of nearly three centuries, to Johns Hopkins in the lusty youth of less than three decades. As President of the College of Physicians of Philadelphia I represent also the oldest institution in America at all similar to your own, a corporation which includes surgeons as well as physicians, and which was already in its teens when the Royal College of Surgeons was founded. On behalf of these and of all our medical institutions we bring you our heartiest greetings on this festal occasion, in the name of sound learning and accurate scholarship.

It has been my pleasure in Philadelphia to welcome many of your Fellows, including three of your most distinguished Presidents. Some of you have even swept across the continent in luxurious palace cars in but little over 100 hours. To show how swift has been our progress and yet how young we are, I need but recall the fact that this College was nearly 40 years old before the name of Chicago—now a city of nearly 2,000,000 people—even appeared upon the map, and when you were founded, beyond the fringe of civilisation on the Atlantic coast the only inhabitants of the vast region from the Alleghanies to the Golden Gate were the buffalo, the bear, and the savage Indian.

But though so young we come not empty-handed. Three great

medical advances mark the past 100 years—vaccination, anæsthesia, and antisepsis. The first and third of these are yours, but the second—anæsthesia—is the gift, better than Magian gold and frankincense and myrrh, which to-day America lays on the altar of science.

Before that historic date, Oct. 16th, 1846, the poor victims of the knife were bound hand and foot and held in the grasp of sturdy men, but hand and cord could not repress the fearful outcries which filled the air. But at Warren's touch the thongs fell off he spoke and the stormy billows of this Gennesaret of pain were stilled; the peaceful blessed sleep of ether hushed every cry of pain. Then first was modern surgery made possible, and what was made possible by our Warren was made safe and successful by your Lister—no, not *your* Lister, but OUR Lister, for his name belongs to no age and no country, but to humanity.

It is, therefore, with a special fitness that to-day you have conferred your Honorary Fellowship upon the distinguished grandson of him who first demonstrated the blessings of ether to a suffering world. At the very time when this College was founded Warren was a student of Guy's Hospital and his certificate of attendance, signed by Mr. Cline and Sir Astley Cooper, is in the possession of his grandson.

Again, Mr. President, I beg you to accept our sincere thanks for the distinguished honour you have conferred upon us.

Professor LANNELONGUE. (*Translation from French.*)

To praise the Royal College of Surgeons of England, with which we have just become connected, and the centenary of which you are at present celebrating, would be to exalt one's own merits.

The duty of a foreigner on whom such a great honour has been conferred should be that of merely expressing his gratitude. However, there are in your past history as a surgical body during this century such achievements to be chronicled that the very mention of which in a few words may not be displeasing to you.

A journey fraught with interesting consequences which was made to England by a famous French surgeon, Roux, showed what you were in 1814. He returned from this voyage with the friendship of a number of the followers of Hunter's methods, such men as A. Cooper, Ch. Bell, Brodie, Travers, Lawrence, and with a knowledge of the secret of the ligature of great vessels, the resections—which were not practised anywhere else—flap amputations, finally, the reunion by intention, facts which were forced upon them. Roux returned in a state of mind divided between admiration of your audacity and mistrust of it. He proclaimed the brilliant features of your practice in surgery, but also did not conceal its imperfections. Such was the origin of a scientific interchange of ideas and discoveries which has never slackened between you and us. The proof of this was illustrated when on March 8th, 1847, Flourens discovered the anæsthetic action of chloroform, and a few months later, on Nov. 10th, 1847, Simpson of Edinburgh employed this agent on man with admirable results.

As early as 1852 Clover praised ischæmia, which does not detract in any way from the merits of Esmarch, and did not ovariotomy flourish in England when there was nothing but failure elsewhere? Another journey was necessary—the one of Jules Worms and Nélaton in 1860—to impel conviction. In short, you have had a man at the right moment who was able to understand the works of a Pasteur and appropriate his principles and thus to establish modern surgical antisepsis.

Gentlemen, to be associated with you is one of the most enviable honours, and we thank you.

Professor V. PACHOUTINE (*who spoke in English*).

I observe amongst the number of illustrious surgeons of many nations elected Honorary Fellows of the Royal College of Surgeons of England the names of some of the surgeons of Russia.

This is a great honour to Russian surgical science which, although in its youth, has produced already a Pirogoff.

I take this opportunity to express to this greatly esteemed College, in the name of all Russian surgeons, their very sincere gratitude for the distinction conferred upon their countrymen, and on their behalf to further express the wish that the Royal College of Surgeons of England may continue to flourish and to give to the world illustrious men, who like their predecessors will be shining lights to the surgical science, ever opening new roads for surgical practice to the benefit of the human race.

THE CENTENARY DINNER.

The centenary dinner was held in the beautiful Hall of the Honourable Society of Lincoln's Inn on the evening of Thursday, July 26th. Sir WILLIAM MAC CORMAC, the President, was in the chair and a large and distinguished company of some 300 was present, including H.R.H. the Prince of Wales, Hon. F.R.C.P., Hon. F.R.C S., the Marquis of Salisbury, Hon F.R.C.S, the Earl of Rosebery, Hon. F.R.C.S., and the distinguished surgeons who had received the honorary diplomas of the College in the course of the afternoon. There were also present among those who did not belong to the medical profession, H.R.H. the Duke of Cambridge, the Portuguese Minister, the Lord Chancellor, Earl Spencer, the Lord Mayor of London, the Duke of Northumberland, the Earl of Kimberley, the Lord Bishop of London, Lord Rothschild, Maharajah Jugga Rao, Lord Davy, Lord Strathcona, Lord Kelvin, Sir Henry Roscoe, Mr. Justice Lawrance (treasurer of Lincoln's Inn), Lord Alverstone, and others.

The PRESIDENT, in proposing "Her Most Gracious Majesty the Queen," said: Your Royal Highness, my Lords, and Gentlemen,—The first toast I have to propose is that of the Queen, God bless her. I know nothing more touching or soul-stirring than to hear as I recently have heard them, in some distant and lonely land, perhaps in front of the enemy, the strains of our national anthem peal out. Let us drink, then, with all enthusiasm the health of the best of women and the greatest of queens.

In giving "Their Royal Highnesses the Prince and Princess of Wales and the other members of the Royal Family," Sir WILLIAM MAC CORMAC observed: I need scarcely repeat, what is well known to this company, what a large part the Prince of Wales takes in the public affairs of this country and the cordial goodwill and affection which his fellow-countrymen entertain for him, and this is not only because he is Prince of Wales, but because his incessant labour for the public good and devotion to every good cause have earned for him our profound respect and esteem. For the beloved Princess his wife every Englishman and Englishwoman, too, entertains the deepest admiration. Her charitable impulses have found further and wider scope in the necessities of the war we are still unhappily engaged in, and it would be difficult to estimate the far-reaching results of her influence. There is another member of the Royal family present whom we should at this time especially delight to honour—I mean His Royal Highness the Duke of Cambridge. There is no man in all Her Majesty's wide dominions more whole-hearted and true, and there is no one more worthy of the respect and affection which he so universally possesses. I call upon you to drink with all enthusiasm the health of our new Fellow, His Royal Highness the Prince of Wales, and that of the other members of the Royal family.

His Royal Highness the PRINCE of WALES, who was received with enthusiasm, on rising to respond said that he did so in a totally new capacity, that of an Honorary Fellow of the Royal College of Surgeons of England. The sister College had already elected him an Honorary Fellow, so that he was indeed one of them and a member of the two professions which did such good to mankind. He was afraid, however, that he would not be allowed to practise the profession, for if he did he very much feared that he might perhaps commit manslaughter or even murder, from the results of which even his good friend the Lord Chancellor would not be able to save him. He then referred to the great progress which had been made in surgery and in graceful terms spoke of the service which had been rendered to him by the President of the College when he (the Prince) two years ago met with an accident. He also alluded to Sir William Mac Cormac's services during the war in South Africa and acknowledged the services of Mr. Treves in a similar capacity. He then referred to the work done by the medical profession in the South African campaign and said he was sure that the members of that profession had done their best and that the way in which the hospitals had been managed reflected the greatest credit on them.

The toast of "The Honorary Fellows of the College" was proposed by Sir WILLIAM MAC CORMAC, who observed: This is the first time this toast has been proposed, as it is only quite recently, as I explained this morning, that we obtained the necessary authority to grant these honorary distinctions. We attach great value to them, and it was our wish to bestow the highest honour in our power on the distinguished persons who have just been made Honorary Fellows of our College. There can be no doubt that the importance and success of this occasion have been greatly enhanced by the exercise of these powers. We are greatly gratified at being able to bestow these honours, and there can be no question that the position of the College is strengthened by the inclusion within its ranks of so many distinguished persons. To you, sir, who stand first upon our roll of honour I should like to say with what enthusiastic acclaim your name as one of us has been received. I know well—indeed, we all know—your generous sympathy and interest in our affairs and your special desire that this centenary celebration should prove worthy of the College and of the occasion. I trust that it has been so. Our great countryman Lord Salisbury has spared the time from the affairs of State to come to do us honour. We are deeply grateful to him and we have tried to make what return was in our power not only to the great statesman but to the altogether admirable chemist, a branch of science of such great importance to medicine. Lord Rosebery's great gifts are known to us all. I was lately asked by an eminent physician to tell him the principle which had guided us in our selection as Honorary Fellows of Lord Salisbury and Lord Rosebery, and my reply was that Lord Salisbury was an eminent man of science and that Lord Rosebery was eminent in everything else. All the other Honorary

THE CENTENARY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND. THE FESTIVAL DINNER IN LINCOLN'S INN HALL.

Fellows are surgeons, the elect of their profession, the glory of their country, and the pride of ourselves. We congratulate them on their newly acquired distinction, and we congratulate our College on the distinction they bestow upon us. Let us drink to the health, long life, and happiness of the Honorary Fellows of the Royal College of Surgeons. I have now to call upon the Earl of Rosebery, Honorary Fellow of the Royal College of Surgeons of England, to respond to this toast.

The Right Hon. the Earl of ROSEBERY, K.G., K.T., Hon. F.R.C.S., in responding, said that he had filled many embarrassing positions, but he had never felt what embarrassment really was until he had been made a Fellow of the College of Surgeons. The Honorary Fellows of the College, for whom he had been asked to reply, represented all the countries of Europe; their names and distinctions occupied three printed pages and constituted a numerical catalogue with which he was not able to deal, but he was glad to say that they had already replied for themselves in the afternoon. That left three Honorary Fellows. The Prince of Wales, however, had already replied, and so now the number was reduced to two—the Prime Minister and himself. He hoped that no one would entrust a surgical case to either his noble friend or himself. The Prime Minister was credited with the intention of performing on the illustrious mother of parliaments an operation which consisted in giving a new lease of life by first stopping that which now existed, and then flinging it into that exhilarating cauldron which would return it to life. He did not know whether the scalpel or knife would be shortly applied in any such way as that, but that was the only surgical operation which he considered could with safety be entrusted to the noble marquis. He thought that if political matters were conducted on scientific principles it would probably be better for the peace of the world. Men of science knew nothing but peace. Science was sometimes defeated, but the defeats of science were the defeats of humanity itself.

The toast of "The Guests" was proposed by Mr. THOMAS BRYANT, who said: The toast which it is my privilege to give on the present interesting occasion is that of "The Guests," who I may honestly say are the choicest representatives of every learned, scientific, artistic, and useful branch of human endeavour which this metropolis can supply. We have been led to make this selection under the conviction that the distinguished Honorary Fellows of this College whom they have been invited to meet are men of equal calibre—for the three professing but not practising Fellows who head our lists are men whom all the world delight to honour and who honour this College by becoming Fellows and thus partaking of its interests, whilst the remaining Honorary Fellows are the leading practising surgeons of the European and American States and of our own much-beloved colonies. In fact, they represent, with the Fellows of this College, the working bees of the surgical profession which utilise to the full every science and art which our guests so ably cultivate, and cull from all branches of human industry everything and anything which can possibly help towards the investigation, the prevention, and the cure of disease. Indeed, I like to think of them as the representatives of applied science for the personal benefit of mankind. They at the same time recognise no rivalry, but only friendly competition which it is to be hoped, under the banner of the Fellowship of the Royal College, will be encouraged for the benefit of the world. The name I have to couple with this toast is the representative of all that is good and all that is great in this highly-favoured Island State—the Lord High Chancellor of England—Lord Halsbury.

The LORD CHANCELLOR briefly replied.

"The Royal College of Surgeons of England, coupled with the name of the President," was proposed by Lord SALISBURY, who received on rising a cordial reception. He said that until he received the Honorary Fellowship of the Royal College of Surgeons he never was a surgeon or as a surgeon proposed the health of surgeons. His colleague in the Honorary Fellowship seemed to think that he (the speaker) knew when the Dissolution would take place. He hoped to elicit from him a secret the knowledge of which he did not possess. He also referred to the fact that the distinguished surgeons who had that day received the Honorary Fellowship of the Royal College of Surgeons of England had come from all countries of the civilised world; and with a few words of acknowledgment of the work and services of Sir William MacCormac he proposed the health of the Royal College of Surgeons of England coupled with the name of the President.

The PRESIDENT, in replying, said: I venture to think that the time for any further speech from me is almost passed, and that I shall do best if I but thank Lord Salisbury for the very kind and handsome manner in which he has proposed the toast which I will call the toast of the evening, the continued prosperity of the Royal College of Surgeons. The inclusions within its ranks of so many distinguished men to-day is a great pleasure and satisfaction to our College, and it is a further and a convincing testimony of the high esteem in which our College is held. As for myself I thank him in all sincerity and gratitude for the kind words he has spoken of me and I do this with all my heart.

At the end of the dinner (during which a selection of music was played by the band of the Coldstream Guards) each guest was presented with a volume containing the Address of Welcome, Centenary of the Royal College of Surgeons of England, by the President and also with a Souvenir of the Centenary of the Royal College of Surgeons of England, 1800 to 1900.

The accompanying picture of the dinner is from a photograph taken by Messrs. Fradelle and Young.

CONVERSAZIONE AT THE MANSION HOUSE.

The concluding entertainment of the centenary celebrations took the form of a conversazione given by the Lord Mayor of London in the Mansion House on Friday, July 27th. A considerable company was present, including many of the Honorary Fellows and other persons of distinction.

Altogether the Royal College of Surgeons of England and its President, Sir William MacCormac, are to be congratulated on a brilliant celebration of the centenary.

THE WAR IN SOUTH AFRICA.

VERY important and stirring events have taken place at the seat of war since we last wrote. The unconditional surrender of Commandant Prinsloo and a large number of Boers at Fouriesburg comes as a great relief after the meagre news of desultory and indecisive movements and fighting which have been taking place of late. The war has not only lasted much longer but has cost a far larger loss of life than it was originally supposed it would do. Still it would now seem to be nearing an end. Further resistance, as far as the Orange River Colony is concerned, may be practically considered as having terminated. It is to be hoped that Lord Roberts will soon have the line behind him restored, in which case he will be able to move upon Koomati Poort and cut off the main source of Boer supplies and so convince Mr. Krüger, when he can no longer communicate with Delagoa Bay, of the folly and futility of any further efforts on his part. We confess that we have never been able to understand why a bold attempt in this direction has not been made before—by General Buller's force, for example. It is useless to speculate on the probable capture of General De Wet's force or that of General Botha, because this has so often failed of being accomplished when it seemed imminent; still the chances of their being surrounded and having to capitulate are increasing. The Boers are still showing great activity in the vicinity of Rustenburg and they have succeeded again in temporarily surrounding General Baden-Powell. All our campaigns in South Africa have been attended with unforeseen difficulties and occasionally with disasters. In spite of the fact, however, that the Boers have succeeded in protracting the war and inflicting a grievous amount of injury on this country, they have not really succeeded in any of their more ambitious attempts and they have failed to exhibit any striking strategical ability. On the other hand, South Africa has proved, as far as the British are concerned, the graveyard of many military reputations. There has scarcely been any branch of the service in the field which has not come in for some adverse criticism, and the commissariat and supply arrangements—especially those in connexion with General Rundle's force—have not escaped. A newspaper correspondent has represented the soldiers of that force as half-starved and in a pitiable condition, and we know all

that has been alleged about the shortcomings of the medical service. This is a very poor recompense for all the toil and hardship entailed by war. According to our reading a clue to the explanation of all such occurrences will be found in the difficulties arising from insufficient transport. It must never be forgotten that the more rapid the movements of an army the harder it is for all transport and supply departments. Mr. James Van Alen, who has just returned to the United States after having been present at Bloemfontein and Kroonstadt in charge of his own field hospital, has stated that the condition of affairs there was worse than ought naturally to be expected in even a rapidly moving army. He attributes this to such causes as the neglect of the sick for the troops and the preference given to the transport of ammunition rather than of hospital supplies, to the single lines of railroad, and to the want of preparation for an epidemic. He thinks that it was a fatal error to have neglected to protect and fortify the water-supply at Bloemfontein and that this oversight accounts for much of the sickness. It is quite possible that this view may be a substantially correct one.

It is clear that when the war is over there must be a very exhaustive inquiry into everything connected with our entire army system and that wholesale changes and reforms will be introduced into it. The progress made in all that relates to modern arms and the munitions and systems of warfare has revolutionised our ideas. The fear is, perhaps, that the reforms in our own army will be based too much upon our experiences with the Boers, and that, as a consequence, we may have in future an army admirably adapted for such kinds of campaign but less effective for other kinds of warfare against trained European armies. Our army medical system will, in any case, undergo great changes in the way of development and organisation.

(FROM OUR SPECIAL CORRESPONDENT LATELY AT THE BASE.)

The feeling that pervades the whole of the medical staff, both civil and military, who are doing, and have been doing, their best in this country for the past nine months, on reading the telegrams from home during the past week is beyond description. They have disheartened beyond measure those of us who have borne the burden and heat of the day. Any stick, we are told, is good enough to beat a dog with, and on this occasion the stick seems to be the so-called "society ladies" whose concentrated wrath has been poured on the whole Royal Army Medical Corps without rhyme or reason. Of course it is not difficult to trace the reason which prompts this semi-hysterical onslaught, and to those of us who are behind the scenes there is a tinge of amusement pervading our resentment; but to the general public, whose only means of knowing what work is being done is by the medium of the daily papers, these accusations and allegations must bear the stamp of genuineness. I am not going to trouble your readers with any defence or excuse with regard to these monstrous complaints. This would only be an insult to a body of officers and men who have loyally, courageously, and with a devotion which would be hard adequately to praise, done their duty in the face of difficulties and dangers that anyone who has not been on the spot can have no idea of. On every hand, I am glad to say, amongst officers and men who have passed through our hands we are daily receiving indignant protests, and they, and they alone, are best able to judge if there has ever been a campaign in the memory of man when officers, non-commissioned officers, and men have been looked after so well and more considerately treated than in this. However, this is our reward, and I am afraid that after this campaign is finished it will take more blandishments than the War Office or Treasury possess to induce worthy men to enter a service the only reward in which is abuse.

I am glad to say that there is a steady diminution of enteric fever in this place, and that the number of admissions to hospital is declining; but of course we are sending home large numbers of men weekly who are unfit to go to the front again. I need not say that we shall gladly welcome the time when once more "peace reigns in the land."

There is a good deal of sickness in Johannesburg and Pretoria, but ample accommodation exists in the various splendid buildings that are found in these two towns, and as trains are now running with regularity, no want of supplies or comforts will be found. Whilst on the subject of comforts, I may say how grateful the men of the Royal Army Medical Corps are for the generous gifts that have been sent out to them, showing that in spite of all some people at home appreciate their efforts.

Bloemfontein, July 8th.

THE FIRST INTERNATIONAL CONGRESS ON MEDICAL ETHICS OR DEONTOLOGY, HELD AT PARIS, JULY, 1900.

(FROM OUR SPECIAL CORRESPONDENT.)

MASSAGE, QUACKS, AND NOSTRUMS.

ON Wednesday afternoon, July 25th, the Congress divided into two sections, and as complaints had been made that the discussions had assumed a purely French and local aspect it was decided that subjects of this nature should be debated in the first section and questions of a more general character in the second section. Consequently I attended the second section. The afternoon was mainly devoted to the consideration of the many and various forms of competition from which medical men have to suffer.

Dr. DIGNAT (Paris) urged that nurses and others who applied water and electric cures were practising medicine, though they were not properly qualified. There was no denying that these agencies might do a great deal of good or, if wrongly applied, a great deal of harm. Then there were the prescribing druggists and the covering doctor. All these were the parasites of the medical profession. Under the supervision of medical men their work was sometimes legitimate and useful, but they had no right to go to families and propose to treat patients unless called in by a qualified medical attendant.

Dr. SALOMON, of the department of the Sarthe, mentioned a medical man who employed a masseur to administer chloroform and a postman who acted both as a masseur and doctor.

Dr. BENEDICK (Vienna) urged prudence. He had always found that the conviction of mesmerists only served to increase the number of their clients. In one case the public prosecutor who had secured a conviction subsequently went himself to consult the quack in question. In Austria also there were many eminent scientists who were not doctors of medicine, and in certain mountainous districts there were no medical men at all. But there were families who had inherited capacities which were probably in the origin based on a true knowledge of medicine. When there was no medical man available the sick could not be prevented from consulting such persons. Also, there were peasants who undoubtedly were wonderful bone-setters—one of them had been nominated honorary doctor by the University of Prague so great was his skill. It was wiser to show some toleration to those who outside the profession undoubtedly had rendered services.

Dr. OTTOLENGHI, from Italy, delivered an amusingly inconsistent speech. He lamented the ignorance of the profession in regard to the so-called occult topics—hypnotism, mesmerism, faith-healing, suggestion, &c.—and then urged that no one but medical men should be allowed to practise those very methods about which he had declared they knew so very little.

Dr. VANDAM (Brussels) argued that there were two sorts of massage, scientific and non-scientific. The former could only be attempted by medical men with perhaps some slight indulgence towards aids. Massage was a specialty in medicine, just like dentistry, and he was of opinion that medical men only should be dentists.

Dr. SEQUEL (Paris) thought that students were too soon allowed to administer chloroform, and this led them to be careless in after life as to whom they employed for this purpose.

Dr. BERTIL BUHRE (Sweden) explained that in his country diplomas were given to gymnasts; consequently they ventured to treat patients without referring their cases to a medical man. On the other hand, as the masseur received no diploma he did not dare to act on his own

responsibility. As for quacks, they were only fined 12s., but an unqualified individual who had attempted to stop a tooth had been fined £40, which showed that the Swedish dentists were better able to protect their interests than were the medical men.

Dr. DUGRON (Paris) said that many patients seen at the hospitals were suffering from serious consequences as the result of incompetent massage. But various classes of healers had formed a strong union or syndicate, with Members of Parliament and even medical men on their committee, and they were better prepared for defence than the medical profession for attack. They called themselves the association of all those who treat patients without medicine; and as they did not give or prescribe medicine they concluded that they could not be prosecuted for the illegal exercise of medicine. Unfortunately, qualified medical men were themselves very poor judges in regard to massage. He urged that massage should be taught and then, with the same inconsistency as the Italian delegate, he claimed for medical men a monopoly of massage, though he had declared that the majority knew little or nothing about the subject. Medical men, however, did know anatomy, and no one ignorant of anatomy should venture to practise massage.

Dr. BENEDICK agreed that all medical students should study massage and that massage should only be practised when controlled by fully-qualified medical men.

Dr. C. PETIT (Paris) raised the question of the sale of medicaments and poisons without prescription. If poison could not be obtained by itself it could always be bought in the form of a specialty or patent medicine. He thought that these specialties should only be sold when prescribed. Medical men alone could judge whether a special or patent drug was good, but the public were left to decide this matter for themselves on the reading of a pamphlet or advertisement.

Dr. BITTLE C. KEISTER (Virginia, America) read a strong denunciation of the so-called "cure-alls" and other nostrums. "About a year ago," he said, "I received a lengthy communication from the editors of a very respectable medical journal requesting my services in writing up some of their advertised preparations. In their letter they took particular pains to compliment my style of writing and insisted upon an immediate reply of my acceptance of their liberal (?) offer of a three years' subscription of their $3 journal for a single 'write up' of two medicines known as 'Viskolien' and 'Micajah's Uterine Wafers.'" Dr. Keister then gave a long list of drugs advertised in America, some in a very improper manner, but he saw "no objection to a carefully prepared and skilfully compounded preparation whose formula is correctly and clearly printed on the label, giving each ingredient its proper place and full sphere of merit." He thought that physicians who prescribed nostrums were acting against the better interests of the profession. It would also be to the better interests of the dispensing chemists if they gave up the nostrum trade, and he concluded by expressing the hope that the time would come "when the ethics of the two professions will be so sacredly and mutually respected that the druggist will disdain to handle in his stock any secret or semi-secret proprietary medicine, and the physician in a like manner will discountenance their use by not prescribing them."

The Section concluded by passing a resolution against the sale of poisons disguised in patent medicaments unless prescribed. It also expressed its opinion that unqualified persons should not be allowed to administer chloroform and that medical practitioners should not dispense drugs.

THE DEBATE ON DEONTOLOGY.

On Thursday morning Dr. GRASSET read his remarkable paper on Deontology, of which I have already sent you a summary. The discussion on this communication was opened by Dr. DE GOUVÉA (Rio Janeiro), who related that medical ethics were at a low ebb till the formation of a medical society in the capital. This produced such good results that similar organisations were created in other parts of Brazil, and now these societies were all federated and the position of medical men from the deontological point of view had consequently greatly improved.

Dr. ANTONELLI (Paris) maintained that such matters could only be regulated by a superior council that should be removed from all local considerations and interests.

Dr. THIÉRY (Paris) said there should be a book for students explaining the principles of deontology.

Dr. MALBEC inquired who would have the authority to draw up such a code.

Dr. VANDAM replied by proposing that an international committee should be elected for this purpose.

Dr. PETERSEN (St. Petersburg) thought the proposal excellent. Each country should have a national committee and there should be a general international committee.

Dr. LASSALE said that in the department of the Gironde the Medical Syndicate had drawn up a code of deontology, but it had in no wise improved the black sheep of the profession.

Dr. ZAMBACCO PACHA (Constantinople) stated that in the East the conduct of medical men was most deplorable. Their alliance with the dispensing chemists was apparent to all. They frequently practised abortion, and in spite of this were not excluded from the learned societies. An international code of deontology could alone remedy this disgraceful state of affairs.

It was finally agreed that at a later stage the Congress would be called upon to vote on the election of an International Commission to deal with the whole question of deontology.

THE MEDICAL CHAMBERS OF AUSTRIA.

The report by Dr. HENRY ADLER (Vienna) on the Medical Chambers of Austria was now read. Many medical congresses had been held before a definite project was approved in 1886 at the Innsbruck Congress, and it was on Dec. 22nd, 1891, that a law instituting these Medical Chambers was passed. The law states that all qualified practitioners must be attached to the Medical Chambers except in the case of a State functionary or an army surgeon, or when a medical man has formally retired from practice. The Chamber has to attend not only to such matters as concern the dignity of the profession but also to sanitary matters affecting the public health. The Chambers must organise all medical competitions that may be held, be ready to express an opinion on medical questions, to advise the authorities, and to act as a court of honour in regard to personal quarrels between members of the profession. In case of misconduct on the part of a medical practitioner the court of honour may, after a reprimand, impose a fine of not more than 200 florins and may finally temporarily or permanently withdraw the culprit's right to practise. The fines paid go to swell the funds of the Chamber. The Chambers themselves are controlled by the local government authority which may rescind the action of the Chambers when they have exceeded their powers. It may even dissolve a Chamber and order a fresh election. These Chambers must consist of at least nine members; that of Vienna has 29 members and the members are elected by the profession every three years. Medical practitioners who are more than 60 years old may refuse to be elected. All the services rendered are honorary. The hopes entertained as to the good effects to result from this institution have not been realised. Firstly, because the Chambers have not power enough to act. The Chambers have been of use in improving the course of medical education and in softening the acuteness of the competition between medical men, but there remain unaltered many abuses. They have had very little influence on sanitary matters nor have they been able to regulate the supply of medical men in accordance to the needs of the various localities. In regard to contract work for friendly societies, the fact that there is a grievance is now at last recognised, and both the State and these societies will soon be made to reckon with the medical profession, but the result will depend upon the energy and unanimity with which medical men support the Medical Chambers.

THE GERMAN MEDICAL CHAMBERS.

Dr. PAUL SCHOBER read a paper on the Medical Chambers in Germany, saying that those of Prussia were the best organised. Their object was to attend to matters affecting public health and all that concerned the honour of the profession. Each of the 12 counties of Prussia had a Medical Chamber, and every 50 practitioners elected one representative member to these Chambers. The elections take place every three years and the votes are sent in writing by post to the president of the local Chamber. The Chambers have the right to make proposals to the local government authorities, especially on sanitary questions, and to be represented on the county sanitary councils by one or two members. Each Chamber has its court of honour, consisting of the president, three members, and a member of a legal Chamber. It can inflict an admonition, a reprimand, a fine not exceeding 3000 marks, and may also disfranchise the guilty member. Any practitioner in Prussia may be summoned before these Courts of Honour

and there is a supreme court of appeal at Berlin. There is also a central committee at Berlin consisting of one member from each Medical Chamber which acts as an intermediary between the Government and the Chambers and between the Chambers themselves. None of these functions are paid but allowances are made for travelling expenses. All medical practitioners have to subscribe, the amount being fixed by the Chamber according to their requirements, and consequently it varies. The fines inflicted are also kept by the Chambers. This institution of Medical Chambers is too new to say much as to the effects obtained; but, on the whole, the medical profession is well satisfied.

Dr. JAFFÉ (Hamburg) protested that there was nothing new in the idea of a Medical Chamber. Those of Bavaria were much older than the Prussian medical Chambers and the same might be said with regard to Saxony, Hesse, and Würtemberg. On the other hand, there were some parts of Germany that had no such organisations. In all cases the first object of a Medical Chamber was to maintain the dignity and authority of the profession. They were, however, in need of a generally accepted deontological code. He also thought that the code of honour governing a medical man engaged in civil practice should apply equally to army surgeons and State functionaries. There should be equality and there could be no difference in matters of honour. Though at Hamburg their Medical Chamber could also inflict a fine of 3000 marks, by far the greatest punishment was the publication of the sentence. He concluded by urging that some such institutions as the Medical Chambers should exist in all countries and that their deontological code should emanate from an international court.

SHIP SURGEONS.

In the afternoon the Congress was again divided into two sections. In the first section the following resolution, proposed by Dr. BOREL and Dr. FAYOL, was adopted:—

Considering that ship surgeons have for mission (at least in France) the duty not only of medical surveillance over their ships but also of protecting the ports they enter from infectious diseases, this mission cannot be faithfully fulfilled if the surgeons are the dependant and paid servants of the ship-owners; therefore the Congress urges that the public authorities should render ship surgeons absolutely independent of ship-owners and that they should be responsible only to the maritime, sanitary, or port authorities.

A MEDICAL STRIKE.

There was also some discussion as to the relations of medical men with the large life insurance companies, it being urged that these should be treated as ordinary clients and no special terms made. Then Dr. BAUDRY (Rennes) related that a medical strike had taken place at Ille-et-Vilaine against the poor relief authorities. The latter proposed to pay the medical men who attended paupers one franc per consultation and one and a half francs per visit, medicine included. The strike failed through the action of some "blacklegs."—The Congress blamed the latter and congratulated the practitioners of Ille-et-Vilaine upon their energy and courage.

Dr. ISSA HAMDY PACHA (Cairo) described the strange situation of a medical man who was calumniated by another practitioner who had violated his pledge of professional secrecy. The victim in this case could not defend himself because to do so he would also have had to violate professional secrecy and therefore had to suffer unjustly.—The Congress approved of this conduct and congratulated the practitioner in question upon his reserve.

MEDICAL SOCIETIES.

In the second section Dr. MANOLESCU (Bucharest) related that a medical association of Roumanian doctors had been formed. It issued a monthly journal, held an annual congress, and discussed both sanitary and medical questions.

Dr. CAYLA described the medical societies of the department of the Seine. Some were 20 and others were 50 years old, but it was only during the last 10 years that they had discussed economical questions. At first these societies had been isolated; now they were united by their General Council.

Mr. ADOLPHE SMITH said that the description given corresponded with the general character of the numerous medical societies existing in England, several of which were over a hundred years old. These societies were highly respectable and rather than admit the black sheep of the profession had in some instances formed medical unions outside of their own ranks, for it was most necessary to bring into line those who were otherwise likely to become "blacklegs." Were the medical societies of France inclined to act in a similar manner?

Dr. DECOR replied that the French medical societies were old and when first established had not foreseen the present economic evolution. But it was a stain to be driven out of such a society or to be refused admittance, and this acted somewhat as a check.

Dr. BELLENCONTRE urged that the duality of societies was quite justified. There were the medical societies that might form the aristocracy of the profession, and there were the medical syndicates or fighting medical unions who would deal with the black sheep, &c.

Dr. CLEMENTS (Bucharest) said that the Roumanian Medical Association was more like the English and French medical sccieties. Medical men of good reputation all belonged to the association. Those whose reputation was more doubtful were put into a sort of quarantine and kept out of the association for a while. There was a general committee at Bucharest which acted as judge in such matters.

Mr. H. NELSON HARDY, treasurer of the British Police Surgeons' Association, read a paper urging that as the medico-legal advisers of the police the surgeons were insufficiently paid. They had to appear as witnesses for the Crown and often the remuneration they received did not cover the expense they incurred.

During the same afternoon Mr. ADOLPHE SMITH read a paper on the Organisation of Medical Unions in England, describing the development of economical forces which had rendered such organisation absolutely necessary. This was really an essay on political economy as affecting medical practice followed by an account of various medical unions formed in England. The paper was listened to with great attention and evoked marks of approval.

In the evening the members met at the Palais d'Orsay, where a banquet was held under the presidency of Dr. BROUARDEL, the Dean of the Faculty. This was the first banquet given in the magnificent hall of the hotel attached to the new station of the Orleans Railway. The band of the 130th Regiment of the Line played selections during the banquet. Of course there were numerous toasts and enthusiastic speeches, which were all the more enjoyable as the members present felt that their Congress had proved successful and wa likely to lead to great things in the near future

INSURANCES FOR MEDICAL MEN.

As usual, there was a certain rush on the last day of the Congress. The papers that had not yet been read had to be hurried forward so as to afford time for the final resolutions which were to complete the work of the Congress. Consequently the sitting began early on the Friday morning when Dr. LANDE'S paper on Mutual Assistance and Insurance for Medical Men was read. First he showed the expense in time and money of medical education, and then that the practitioner's income depended on his health, and was rarely sufficient to admit of his saving any considerable sum. Therefore the practitioner should insure his life early when the premium to be paid would not be high. Unfortunately, medical men were, as a class, somewhat improvident. The paper then described the various charitable or semi-charitable institutions existing in different countries that were likely to help practitioners in distress. After hearing all these details the Congress endorsed the conclusions of the report which were to the effect that the means of insurance for medical men were not yet sufficiently developed, that there should be insurance against sickness and old age as well as against death, and that there should also be a fund for old-age pensions. Finally, medical men should not only pay annually insurance premiums for their own personal benefit, but they should also pay a small sum, be it only 10 francs a year, to create a general fund for the aid of any exceptional distress occurring among members of the profession or their families.

THE FORMATION OF MEDICAL UNIONS OR SYNDICATES.

The paper on the Organisation of Medical Defence was taken next. It was written by Dr. SALOMON, member of the Administrative Council of the Union of the Medical Syndicates of France. Dr. Salomon considered that the medical profession had fallen in a great measure from its former high estate. Medical men had failed to notice the tremendous transformation going on around them. Other classes of the community had armed themselves, formed powerful associations, trades unions, coöperative societies,

benefit societies, and sick funds. What had the medical men done? Formerly no one outside the profession knew anything at all about medicine and they had to depend entirely on the medical man. Now with the spread of education, the literature of patent drugs and specialities, any number of people doctored themselves and rarely resorted to the advice of a medical practitioner. Others obtained such advice for a mere nominal sum through the agencies of friendly societies or for nothing from the hospitals. In the meanwhile medical men avoided each other, indulged in rivalries and antipathies, and by reason of their disorganised and divided condition became a ready prey and the victims of numerous forms of exploitation. It was said that there were too many medical men. The evil rested rather in the fact that too many medical men crowded together in large centres. Within the last ten years the number of practitioners had doubled in the departments of the Seine (Paris), Seine et Oise, Rhône, Nord, Bouches du Rhône (Marseilles), and Seine-Inférieure (Havre). Yet in other, especially rural, districts there were not enough medical men. There were also far more foreign medical men practising in France than there used to be. The author of the paper then reviewed at length all the causes that tended to diminish the possible income of medical practitioners, poor relief, charities, friendly societies, hospitals, improvement in the public health, prescribing chemists, the illegal practice of medicine, &c. The second portion of the report dealt with such measures of defence as had been attempted and mentioned that the honour was due to Orfila of having founded in 1833 the first French medical association. It was L'Association des Médecins de la Seine. Then in 1859 L'Association Générale des Médecins de France was established chiefly for the purpose of helping medical men in distress. But they also gave moral support in professional questions. The General Association and its branches were described as something less than a syndicate or union but something more than a mere charitable or benefit society. But the General Association of French Doctors had no mandate or authority to defend professional interests and nothing further was attempted till the year 1880, when the first medical syndicate was founded at Montaign, in the Vendée, by Dr. Mignen—unless the *Concours Médical*, which was founded in 1879, be taken as its precursor. This latter had been the work of Dr. Cézilly, whose absence from the Congress through illness led to a demonstration in his honour and to expressions of sympathy. When the number of syndicates had increased they formed a union of syndicates under the presidency of the late Dr. Gibert of Havre. In 1885 there were 40 medical syndicates in France. But the movement was in a great measure checked by the verdict given by the Tribunal of Domfront which declared that the law of March 21st, 1884, which gave a legal standing to syndicates, only applied to workmen's syndicates or trades unions. Now, however, a new law, that of Nov. 30th, 1892, on the practice of medicine, granted to the members of the medical profession the same rights as had already been acquired by the working classes, with this exception, however, that medical syndicates might defend the interests of the profession against all persons except the State, the Departments, and the Communes. Thus the powers and action of medical unions in France were more restricted than were workmen's unions. Of course, the medical profession would not rest satisfied till this disability was removed. Dr. Salomon then went on to say: "We are reproached for having imitated the workmen without perceiving that the necessities of our professional life place us nearer to workmen than to employers. As our colleague Dr. Chantemps said, 'We are workmen, the *élite* of the working-class if you like, but as skilled artisans we are alone in the accomplishment of our work—we do not pay wages to others to work for us.' This opposition explains many abstentions. The syndicate of the Seine, for instance, has only about 1000 members out of some 3000 practitioners. Not that our syndicate, like the other syndicates, has failed to render itself sympathetic, but because the greater number of our colleagues obey sentiments of selfishness, which prompt them to attend only to their own individual affairs, and does not allow them to pause to consider general interests or to trouble about confraternal relations and the future of the profession. Further, we must recognise that the syndicates have systematic irreconcilable opponents. These enemies are of two sorts, those who are at the top, and those who are at the bottom, of the ladder. At the top are the successful medical men who have nothing to fear from a crisis in the profession, who often do not even understand the dangers that menace the profession. At the bottom are poor, unscrupulous, wretched individuals of all sorts, who have to resort to all manner of stratagems to secure a bare existence and who keep away from us so that we should not see what they do." In spite of all this the cause was gaining ground daily. The report then went on to relate that the Medical Syndicates had succeeded in causing the law to be more strictly applied in prosecuting quacks, in bringing grievances to the front, and produced some improvements in raising the tone of the profession, and in engendering a more brotherly feeling among practitioners.

When the discussion was thrown open Dr. DUPLESSIS eloquently pleaded in favour of liberty while to-day everyone was seeking to establish rules and checks. He thought that the only check should be a moral check. He strongly objected to have the conduct of a medical man judged by a lawyer. The latter could never understand the ethics of a man of science. The lawyer adhered rigidly to the text of a law; the man of science knew that what was thought to be the truth yesterday had been proved false to-day, and what they now believed might be demolished to-morrow. By all means let moral restraint be brought to bear, but there must be no compulsion.

Dr NOIR replied that the liberty of to-day could not rest on the same basis as that of yesterday. The economic evolution had altogether changed the basis. To-day they had to abandon a great deal of their individual freedom in favour of the spirit of solidarity and so as to acquire the power of resistance.

Mr. ADOLPHE SMITH said there was no freedom for the man who was starving—he had to sell himself to the first bidder. He had more freedom in submitting to the discipline of his professional union than to the tyranny of a taskmaster who profited by his isolation and helplessness. So far the Congress had been mainly useful in bringing forward a long list of grievances. It was time to pass from the diagnosis to the prescription of remedies. United, the profession was the absolute master of the situation; the great battle, therefore, would be, not against outsiders, but against medical men who refused to unite. The medical man was the principal foe of the medical profession. Thus, for instance, at Wolverhampton and Coventry the medical unions of those towns would have been successful recently had not medical men from Birmingham come to consult with ostracised practitioners in those two towns. On the other hand, the consultants of Norwich had refused to act in a similar manner on behalf of the ostracised practitioners at Great Yarmouth. How were the more prosperous members of the profession to be brought into line? For his part he thought that there had not been sufficient use made of the weapon of publicity; and even if this were to lead to prosecutions for libel, or in France to arrest for attempting to interfere with the freedom to work, no great cause had lived without its martyrs and a public trial was the cheapest form of publicity, the most effective means of propaganda.

After some further discussion the following resolutions were carried:—

1. For the purpose of preservation and of professional defence all medical practitioners should unite and act according to the principles of solidarity.
2. This union and this solidarity will be established by the organisation of societies which may be at once chambers of discipline and associations for professional defence.
3. The syndicate will more especially take in hand the work of professional defence, for it alone has the necessary attributes to struggle against the attacks made by society upon our monopoly.
4. There should be but one syndicate per department, so that all members of the syndicate shall have to submit to the same rules.
5. The same union and solidarity should exist between the syndicates as exists between the members of the syndicates. They will thus form the syndical union and the union of the syndicates.
6. The union of the syndicates shall form, for France, a single federation for the entire territory. It shall be the agent of centralisation and of decentralisation, and ought to be officially invested with the power to go to law as the representative and in the stead of any one affiliated syndicate.

After this important vote the Congress adjourned.

THE MEDICAL ASSOCIATION OF NORWAY.

In the afternoon the Congress at first divided into two sections and subsequently met collectively to close the proceedings. In the first section Dr. HANSSON (Christiania) gave some account of the Norwegian Medical Association. It had drawn up a deontological code dealing with the relations of medical men towards medical men. It also treated the question of sick club practice and laid down as

a principle that the post of medical officer to such institutions was not to be accepted unless with the consent of the local branch of the Medical Association. They had secured an increase amounting to 75 per cent. on the sum paid to medical officers of these clubs previously to 1888. The association had likewise established and maintained a minimum for country practice, but then about 90 per cent. of the medical men in Norway belong to the association. This was in itself a sufficient explanation of these remarkable successes.

MEDICAL CHARLATANS.

Dr. LASSALE then spoke about medical charlatans. It was a mistake, he said, to believe that all charlatans were outside the profession and illegal practitioners. There were two means of action—conscience and the law. Those who had a conscience had no need of the law; those who had no conscience must have the law. The profession should organise its own police which should warn the public against the charlatans who were within the ranks of the profession. He was in favour of discipline as well as of liberty. While they talked about liberty their difficulties and misery increased. Besides, if liberty was unnecessarily and vexatiously interfered with the profession could easily change those whom it had placed in command.

Dr. BENEDICK (Vienna) said that he considered that the Austrian Medical Chambers had taken some false steps and he was now fighting against some details of their policy. Nevertheless, he was very glad that these Chambers existed. Every institution had its good and its bad side. He was in favour of Medical Chambers possessing extensive powers. There would be abuses and conspiracies, intrigues, troubles, and quarrels; but all this could be cured by the vote of the members, and in any case the good would outbalance the evil.

Some discussion ensued as to the advisability of forming an Order of Doctors, but the hour was too advanced to go seriously into this matter.

THE CONCLUDING SCENE.

At about 5 o'clock the members from the other section returned to the great amphitheatre of the École de Médecine and the Congress, sitting as a whole, at once proceeded to discuss where and when it should meet again. A proposal that it should meet in the same town as that in which the International Medical Congress met was rejected on the ground that the Congress should meet where the movement in favour of forming medical unions or syndicates had most need of its presence. It was finally decided that the Congress would meet in three years' time in Belgium. Then a great deal was said about an international committee which should meet and try to draw up a deontological code. Beyond a general feeling that this ought to be done, that the committee which had organized the congress, and Dr. Vandam who had made the proposal, should help in the work, nothing very decisive was voted. No names were proposed of members to constitute this committee, and the matter at present assumes merely the character of a pious wish. Nevertheless, it is probable that something will be done and a project presented to the next Congress.

A number of resolutions carried in the sectional meetings were read out. Some met with approval, others were referred to the French National Congress as being of too local a character, and then Dr. LEREBOULLET rose to close the Congress. He spoke with feeling of the gratitude that was due to all who had so efficiently helped this first and most difficult step towards the international organisation of the medical profession for the purpose of defending its ethical principles and economic interests. With deep emotion he declared himself convinced that a great and good work had been accomplished.

Dr. VANDAM moved a vote of thanks from the Congress to its President, Dr. Lereboullet, to the secretary, Dr. Jules Glover, and to all the other French organisers, which was cordially awarded.

With cheers and many friendly salutations and expressions of mutual goodwill the members of the Congress dispersed.

Paris, July 30th.

VACCINATION EXPENDITURE.—At the meeting of the Falmouth Board of Guardians, held on July 26th, it was reported that the vaccination fees during 1898 and 1899 amounted to £17 and £26 respectively. For the first six months of 1900 the fees amounted to £255.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary Comitia was held on July 26th, Dr. W. S. CHURCH, the President, being in the chair.

The PRESIDENT announced that the Bradshawe Lecture would be delivered on Nov. 6th by Dr. Archibald Garrod on "The Urinary Pigments and their Pathological Aspects."

Dr. Gee, Sir R. Douglas Powell, and Dr. F. Andrewes were nominated to adjudicate on the Weber-Parkes Prize for 1901.

The following gentlemen having passed the required examination were admitted Members of the College: Alexander Gunn Auld, M.D. Glasg., Noel Dean Bardswell, M.D. Edin., L.R.C.P., Arthur John Cleveland, M.D. Lond., L.R.C.P., Henri Dardenne, M.D. Edin., Francis Woodcock Goodbody, M.D. Dub., Francis Henry Hawkins, M.D. Edin., Thomas David Lister, M.D. Lond., L.R.C.P., Wilfrid Brougham Warde, M.D. Lond., L.R.C.P., Thomas Rowland Charles Whipham, M.A., M.B. Oxon., L.R.C.P., and Oliver Key Williamson, M.A., M.B. Camb., L.R.C.P.

Communications were received (1) from the Secretary of the Royal College of Surgeons of England; (2) from the Director-General, Medical Department of the Navy, on the registration of volunteers for emergency service as surgeons in the Royal Navy; and (3) from the Vice-Chancellor of the University of London, requesting the College to elect two Fellows to be Members of the Senate of the University. Dr. P. H. Pye-Smith and Dr. W. H. Allchin were elected Senators.

On the proposal of Dr. NORMAN MOORE, seconded by the REGISTRAR, the following motion was carried by acclamation:—

That a vote of thanks and the sum of 100 guineas be given to Dr. Allchin as an acknowledgment of his services during several years and on numerous occasions as secretary to the University Committee, as representative of the College before the Royal Commissioners and the Prime Minister, and in many other ways in relation to the reconstruction of the University of London.

On the recommendation of the committee of management the following institutions were added to the list of institutions recognised by the Examining Board in England: (*a*) For instruction in chemistry, physics, and practical chemistry, the Municipal Technical School, Halifax, and the Modern School, Bedford; (*b*) for instruction in chemistry, physics, practical chemistry, and biology, the Technical College, Huddersfield, and the Municipal Technical College, Derby.

Reports were received from the representative of the College on the General Medical Council, from the Fever Hospitals Committee, from the Finance Committee, from the Library Committee, and from the curators of the museum. By-law 103, as amended to make it conformable to the conjoint regulations, was re-enacted a second time.

The Moxon medal was awarded to Sir William Tennant Gairdner, K.C.B., F.R.S., M.D. Edin., Emeritus Professor of Medicine in the University of Glasgow, as having pre-eminently distinguished himself by observation and research in clinical medicine.

The adjudicators of the Weber-Parkes prize reported that they had been unable to award the prize as no essay of sufficient merit had been presented.

The following were appointed censors and examiners for the ensuing year. Censors:—William Cayley, M.D. Lond.; Charles Theodore Williams, M.D. Oxon.; Sir Dyce Duckworth, M.D. Edin.; and Thomas Henry Green, M.D. Lond. Examiners:—Chemistry and Chemical Physics: Percy Faraday Frankland, Ph.D., F.R.S.; Frederick Daniel Chattaway, Ph.D., D.Sc.; Arthur Pillans Laurie, D.Sc.; Henry Wilson Hake, Ph D.; and Henry Foster Morley, D.Sc., F.C.S. Materia Medica and Pharmacy: Francis Warner, M.D. Lond., William Carter, M.D. Lond., Hector William Gavin Mackenzie, M.D. Edin., Edwin Cooper Perry, M.D. Cantab., and James Calvert, M.D. Lond. Physiology: Marcus Seymour Pembrey, M.D. Oxon., John Sydney Edkins, M.B. Cantab., and Robert Arthur Young, M.D. Lond. Anatomy: George Robertson Turner, F.R.C.S. Eng., L.R.C.P. Lond., and Alfred William Hughes, M.B. Edin., F.R.C.S. Eng. and Edin. Medical Anatomy and Principles and Practice of Medicine: Joseph Frank Payne, M.D. Oxon., Sir Thomas Lauder Brunton, M.D. Edin., Thomas Barlow, M.D. Lond., Francis

de Havilland Hall, M.D. Lond., Herbert Isambard Owen, M.D. Cantab., Percy Kidd, M.D. Oxon., John Abercrombie, M.D. Cantab., Nestor I. C. Tirard, M.D. Lond., Donald MacAlister, M.D. Cantab., and William Hale White, M.D. Lond. Midwifery and Diseases peculiar to Women: Charles James Cullingworth, M.D. Durh., John Phillips, M.D. Cantab., Amand J. McConnel Routh, M.D. Lond., C. Montagu Handfield-Jones, M.D. Lond., and Robert Boxall, M.D. Cantab. Public Health: Part I., James Lane Notter, M.D. Dub.; Part II., William Henry Corfield, M.D. Oxon.

Professor Clifford Allbutt, Regius Professor of Physic at Cambridge, will deliver the Harveian Oration on Oct. 18th (St. Luke's Day). Dr. Henry Head has been appointed the Goulstonian Lecturer, Dr. J. F. Payne the Lumleian Lecturer, and Dr. W. D. Halliburton the Croonian Lecturer for 1901, and Dr. J. W. Washbourn the Croonian Lecturer for 1902.

THE FIRST INTERNATIONAL CONGRESS OF THE MEDICAL PRESS HELD AT PARIS, JULY, 1900.

(FROM OUR SPECIAL CORRESPONDENT.)

THE OPENING CEREMONIES.

ON Thursday afternoon, July 26th, the inaugural ceremony of this Congress was held at the Press Pavilion on the Exhibition grounds. Detained at the International Congress of Deontology I could not be present, but from what I heard from those who attended and from papers remitted to me I am able to give some account of the proceedings. It appears that there was quite a demonstration when Professor Virchow of Berlin arrived. Everyone rose and sought to manifest his respect for the eminent German *savant*.

Professor CORNIL opened the proceedings. He welcomed Professor Virchow who for 60 years had grouped in his *Archives* the writings of the most learned Germans. In France also the medical press had grown and could now boast of some 30,000 readers. It reflected medical life and should help to teach medical men what were their duties and what were their rights. Modern progress had been achieved by two scientific revolutions, first the pathological conception of the cellules, and secondly the Pasteur doctrines. The medical press had largely contributed to spread these new teachings.

M. MILLERAND, Minister of Commerce, who had entered while Professor Cornil was speaking, now rose and claimed that he also had been a member of the press and would doubtless return to journalism when his Ministerial career was at an end. If to-day they had scientific journalism as distinct from ordinary journalism, this was due to the natural economic evolution which classified and sub-divided labour. Besides many of the questions to be discussed interested the entire press, such as, for instance, the division between legitimate publicity and that form of publicity which tended to degrade the journalistic profession. It would be a great honour for the Congress should it be able to deal with such delicate matters. He concluded in welcoming all the foreign delegates and especially Professor Virchow.

Professor LANDOUZY recalled the fact that the first newspaper published in France was founded by a medical man and that Renaudot's Journal sometimes dealt with medical matters. The press, he said, was the most universal of universities and it would be the mission of the medical press to aid the Government to solve all matters affecting the interests of the profession.

Professor VIRCHOW congratulated the Association of the French Medical Press on having taken the initiative in organising an international congress of the medical press. He was happy to think that the creation of an international association might result from the Congress and thought that it was quite right for the medical press to meet apart from the Medical Congress.

After the election of the officers for the Congress all the members went by a special steamer to the Hôtel de Ville, where they were received by M. Grébauval, President of the Paris Municipal Council, and by M. Lépine, Prefect of the Police.

Professor CORNIL introduced the delegates and pointed out the importance of the medical press, as there were now actually 300 medical papers published in France. It is to be hoped that on this occasion Professor Cornil omitted to mention that the medical press had 30,000 readers, for as this would mean an average of only 100 readers per journal it does not say much for at least some of these publications. Professor Cornil was more happy when he described the practical services of the medical press and how Berlin owed its sewers and its sewage farms to the active press propaganda led by Professor Virchow.

Both M. GRÉBAUVAL and M. LÉPINE made suitable replies and then led the delegates to a well-supplied buffet.

NEWSPAPER PUFFS.

The Congress began business on Friday morning in the great amphitheatre of the École Pratique at the Faculty of Medicine. Professor CORNIL was in the chair. The Government delegates of the foreign medical press were first called upon to speak, and Dr. MENDIZABAL, of the *Gaceta Medica* of Mexico; Dr. GALLET, in the name of the Belgian medical press; Dr. DIAKONOW, for the Russian medical press; Professor BROSSI for Italian journals; Dr. HANSSON for the Norwegians; Dr. EHLERS for the Danes; and Dr. POSNER for the German medical journals, all made short congratulatory speeches.

Dr. MARCEL BAUDOUIN then described his system of tabulating and registering all scientific publications in a manner that greatly facilitated researches. This was followed by a discussion on the sort of advertisements that might be published in a medical paper. The great question related to what is known in France as a *réclame*, a term which may be generally taken to mean a puff. Of course, it is easy in discussing to confuse the issue. Notices and criticisms even when favourable to an article which has a commercial value may be quite legitimate. What is illegitimate is that such notices should be paid for as if they were advertisements. Dr. POSNER protested that such *réclames* were unknown in Germany.

In France, to make matters worse, papers redolent with *réclames* were now being distributed gratuitously to the members of the profession.

A report on Gratuitous Medical Journals by Dr. LABORDE and Dr. ROMME was read in which they urged that advertisements must be relegated to a special distinct part of the paper and not inserted in all directions.

The discussion was adjourned till the next day.

Dr. BLONDEL urged that medical papers should not publish advertisements of drugs if these were likewise advertised in the general political press.

After discussing without coming to any particular decision the question of newspaper exchanges Dr. DE MAURANS read a paper urging that efforts should be made to adopt a unique international classification for scientific terms. The morning sitting was terminated by Dr. DOYEN who reproduced by a kinematograph several operations which he had performed. This exhibition excited much interest and admiration; its practical utility, especially for students, was highly appreciated.

At the afternoon sitting Professor C. RICHET spoke on the necessity of decimal classification of periodic journals. In the 16 volumes of the Index Catalogue, which dates back 20 years, there were already 1,097,535 separate titles of articles. The decimal system consists of placing in nine separate categories all phases of human knowledge. Each of these would be subdivided into another nine.

This was followed by the reading of a paper on the Question of Copyright by M. POUILLET, M. ROCHER, and Dr. DE MAURANS.

After a few words of discussion Dr. MARCEL BAUDOUIN followed with his paper on the Property of the Idea. A summary of both these papers was published in THE LANCET of July 21st last and therefore I need not refer to them again. As a result of the discussion that followed on the reading of these papers the Congress adopted a resolution to the effect that Article 7 of the Literary Convention of Berne should apply to the medical press. As for the property of the idea, after some discussion this complex question was referred to future congresses. After another and long discussion on the copyright of newspaper articles, a resolution was carried to the effect that newspaper articles, criticisms, &c., should not be quoted without mentioning the name of the author and the publication. With regard to the reproduction of lectures delivered before learned societies the general custom was to ask the professor

permission to print some account of what he had said, and as a rule such requests were not refused.

This concluded the day's sitting and the members of the Congress were conducted to Professor Richet's laboratory, where they took wine together.

(To be continued.)

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6531 births and 4313 deaths were registered during the week ending July 28th. The annual rate of mortality in these towns, which had increased from 14·5 to 16·4 per 1000 in the three preceding weeks, further rose to 19·4 last week. In London the rate was 21·0 per 1000, while it averaged 18·3 in the 32 provincial towns. The lowest death-rates in these towns were 11·1 in Derby, 11·4 in Bolton, 11·5 in Huddersfield, and 11·6 in Bristol; the highest rates were 22·0 in Leeds, 22·1 in Sheffield, 24·1 in Salford, and 28·0 in West Ham and in Liverpool. The 4313 deaths in these towns included 944 which were referred to the principal zymotic diseases, against 427 and 555 in the two preceding weeks; of these 662 resulted from diarrhœa, 88 from whooping-cough, 76 from measles, 66 from diphtheria, 27 from "fever" (principally enteric), 24 from scarlet fever, and one from small-pox. The lowest death-rates last week from these diseases occurred in Wolverhampton, Bristol, Burnley, and Gateshead, and the highest rates in West Ham, Liverpool, Salford, Leeds, and Sheffield. The greatest mortality from measles occurred in Brighton, Swansea, Derby, and Huddersfield,; from scarlet fever in Blackburn; from whooping-cough in West Ham and Sheffield; from "fever" in Portsmouth; and from diarrhœa in West Ham, Liverpool, Salford, Leeds, and Sheffield. The 66 deaths from diphtheria included 27 in London, 10 in Leicester, six in Sheffield, five in West Ham, and four in Leeds. One fatal case of small-pox was registered in Blackburn, but not one in any other of the 33 towns. The number of small-pox patients in the Metropolitan Asylums Hospitals, which had been 17, 17, and 14 at the end of the three preceding weeks, had further declined to 11 on Saturday last, July 28th: three new cases were admitted during the week, against four, four, and one in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1859, against numbers increasing from 1754 to 1877 on the seven preceding Saturdays; 207 new cases were admitted during the week, against 229, 208, and 222 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 160 and 169 in the two preceding weeks, further rose to 196 last week, and were 19 above the corrected average. The causes of 54, or 1·2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Bradford, Hull, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, Manchester, and Newcastle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·2 and 19·0 per 1000 in the two preceding weeks, declined again to 17·5 during the week ending July 28th, and was 1·9 per 1000 less than the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 10·6 in Leith and 13·0 in Dundee to 18·9 in Glasgow and 19·3 in Paisley. The 541 deaths in these towns included 36 which were referred to diarrhœa, 24 to measles, nine to scarlet fever, nine to whooping-cough, six to "fever," two to small-pox, and one to diphtheria. In all 87 deaths resulted from these principal zymotic diseases, against 73 and 102 in the two preceding weeks. These 87 deaths were equal to an annual rate of 2·8 per 1000, which was 1·4 per 1000 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 23 and 38 in the two preceding weeks, declined again last week to 36, of which 23 occurred in Glasgow and six in Aberdeen. The deaths from measles, which had been 17 and 18 in the two preceding weeks, further rose to 24 last week, and included 18 in Glasgow and five in Edinburgh. The fatal cases of scarlet fever, which had been seven and five in the two preceding weeks, rose again last week to nine, of which five were registered in Glasgow and three in Paisley. The deaths from whooping-cough, which had been 21 and 22 in the two preceding weeks, declined to nine last week, and included eight in Glasgow. The six deaths referred to different forms of "fever" showed a decline of five from the number in the preceding week, and included three in Glasgow and two in Dundee. The fatal cases of small-pox, which had been two, one, and two in the three preceding weeks, were again two last week, and were both recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 71 and 80 in the two preceding weeks, declined again last week to 67, but slightly exceeded the number in the corresponding period of last year. The causes of 31, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 17·8 to 23·4 per 1000 in the three preceding weeks, declined again to 18·3 during the week ending July 28th. During the past four weeks the death-rate in the city has averaged 19·4 per 1000, the rate during the same period being 16·2 in London and 17·2 in Edinburgh. The 123 deaths belonging to Dublin registered during the week under notice showed a decline of 34 from the number in the preceding week, and included five which were referred to the principal zymotic diseases, against six, eight, and 13, in the three preceding weeks; of these, four resulted from diarrhœa, and one from diphtheria. These five deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate during the same period being 4·7 in London and 1·3 in Edinburgh. The fatal cases of diarrhœa, which had been two, one, and four in the three preceding weeks, were again four last week. The mortality from diphtheria also corresponded with that in the preceding week. The 123 deaths in Dublin last week included 24 of infants under one year of age and 33 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the numbers recorded in the preceding week. Four inquest cases and four deaths from violence were registered; and 39, or nearly a third, of the deaths occurred in public institutions. The causes of five, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

AFFAIRS IN CHINA.

ALTHOUGH there is every reason to hope that our worst fears regarding the Legations at Peking have not been realised up to the present time it is clear that an advance on the part of the Allied Powers will have to take place—if, indeed, it has not already begun. The undertaking is a large and formidable one both in its political and its military aspects. The task of taking part in it has occurred at an unfortunate time for this country, which is already occupied with a big war elsewhere. The Indian contingent is, as we have already said, accompanied by field hospitals, hospital ships, and medical establishments from India, and a number of medical officers from the fleet will, no doubt, be available to take part in the expedition, together with some officers of the Royal Army Medical Corps serving with the troops in China. As regards the German force, it will probably be accompanied by a large medical contingent, as any number of medical officers and members of the civil medical profession are available in that country for army requirements. We shall see how the Germans, Russians, and other Powers who are not embarrassed by having any other war in hand, manage to carry out the medical part of the forthcoming campaign in China, especially as, probably for the first time in their experience, they will have to convey their troops there by sea transport.

THE SUPPLEMENTARY ARMY ESTIMATES.

The Army Medical Service formed the subject of a good deal of discussion on the occasion of the House going into

Committee of Supply on the Supplementary Army Estimates. There is, however, no need to go over all the ground again at the present time, because our readers are already familiar with most of the points that were raised. It is well known that the strength of the medical establishment was dangerously low at the outbreak of the present war in South Africa and that it had to be reinforced by the employment of a large number of civil surgeons. Moreover, the occurrences in China, the West Coast of Africa and elsewhere, have vastly increased the demand for medical officers in the public services at the present time. It is only fair to say, however, that the present Secretary for War did much more than his predecessors had done to restore the popularity of the service, but whether it were owing to want of time or from other causes these measures have not so far been productive of the effect anticipated. As the matter stands at present the whole subject of the organisation of the army medical services and the provision of an independent medical transport and a large medical reserve will have to be taken up and most carefully considered at the close of the present war in South Africa.

THE SOUTH AFRICAN COMMISSION.

It would, of course, be premature and improper to discuss the subjects under investigation by the Commission, but we may nevertheless advert to the published evidence given by one of the invalided soldiers at Netley. His testimony has, of course, no pertinence or weight in regard to what was alleged to have taken place elsewhere and outside his own experience, but it exhibits such a fine type of soldierly qualities that it is well worthy of being recorded in our columns. "No. 7. Had been in the Indian Mutiny, China, and Abyssinian wars, and left New Zealand as a volunteer, paying his own expenses, and joined the local forces. Wounded in the spine at Paardeberg. Never was more surprised in his life than when he went down to the field hospital and found the comfort and provision which were made for the sick and wounded. Only one in a hundred made any kind of complaint, and those ought to take their mothers with them wherever they went."

AN UNDESIRABLE MEMBER OF THE ROYAL ARMY MEDICAL CORPS.

A youth aged 18 years, named Arthur Deighton, charged with violently assaulting the police, was sent to prison by Mr. Bros from the Clerkenwell Police-court on July 31st for 21 days. After some disorderly conduct he was arrested by a police constable, but six members of the force and a civilian were required to take him to the station. The prisoner, who wore an old khaki uniform, said that he belonged to the Royal Army Medical Corps, that he had been invalided home from South Africa, and that he was now on furlough. If this statement be unfortunately true we can only regret that such a person should ever have been admitted to the Royal Army Medical Corps. But if he is a member the authorities will no doubt see that he has no further opportunity of disgracing it.

DEATHS IN THE SERVICES.

Deputy Inspector-General Rinso Robert Siccama, M.R.C.S. Eng., L.S.A., R.N. (retired), on July 19th. Mr. Siccama received his medical education at King's College Hospital, London, and qualified M.R.C.S. and L.S.A. in 1857. He shortly afterwards entered the Royal Navy as a surgeon and retired some years ago with the rank of deputy inspector-general of hospitals. After his retirement he settled in Bath and soon made himself very popular. Taking an interest in municipal matters he represented the Landsdown Ward in the Bath city council. Recently he resigned his seat and went to Weymouth for the benefit of his health, where his death took place. Much regret is felt in Bath at his decease.

TRANSVAAL WAR NOTES.

The following steamships have arrived at Southampton: the *Nubia* on July 25th, the *Aurania* on July 26th, and the *Manchester Port* on July 28th. They brought respectively 272, 620, and 313 sick and wounded men from South Africa who were admitted to the wards of the Royal Victoria Hospital, making a total of 1205 admissions in four days.

Dr. A. Conan Doyle and Professor A. Ogston arrived in England on July 27th from South Africa.

Correspondence.

"Audi alteram partem."

"ADDISON'S DISEASE AND LEUCODERMA."

To the Editors of THE LANCET.

SIRS,—Writing, as I do, away from my notes and references, I shall not do more than reply as shortly as possible to the important communication of Sir Samuel Wilks in THE LANCET of July 28th. I am sincerely glad, however, that he has at length broken the silence which I inferred from my previous attempts to "draw" him that he preferred to maintain. For I need scarcely add that, apart from personal regard for him, which is that of all his friends, all the world will join with me in holding that if any point about Addison's disease can really be settled by authority Sir Samuel Wilks is the one living authority on the subject.

But a "law of nature"—or an "apparent exception" thereto (I fully accept the implication here implied)—cannot be dogmatically disposed of by mere authority. It is not because Newton wrote the "Principia" that we accept its conclusions or believe even in the law of gravitation. And it may be permitted to me to maintain, in the face of Sir Samuel Wilks's opinion, that the relation of leucoderma to Addison's disease is not settled by anything he has written upon the subject up to now. But his last communication to you unquestionably tends to clear the position, and I hope this imperfect reply will do so still more. I am not, indeed, disposed to admit (and I doubt whether it is intended to be conveyed) that in my lecture to the Medical Graduates' College I attributed to Sir Samuel Wilks any views that he does not in point of fact hold. If there is anything to be regretted, in my opinion, it is that he has been led by his attitude in this communication into even seeming to affirm that the continuity of the pigmentation—the "uniform staining of the skin"—in Addison's disease is to be regarded as a "law of nature." That in the very great majority of the cases the pigmentation is continuous, as Addison, Wilks, and Greenhow all describe it, is not (so far as I know) disputed. Indeed, it has occurred to me to have to demonstrate cases of Addison's disease to clinical classes in which there were present natives of India, and I have been restrained only by personal considerations from pointing out in words the very exact resemblance of the tint in the patient to that of the members of the class aforesaid But vitiligo (apart from Addison's disease) is generally reputed to be much more common in the dark races than among Europeans; and, if so, why should it not also appear among the accidents (if we may so call them) of the Addisonian pigmentation? Furthermore, if Dr. Radcliffe Crocker is right (but I am citing him only on the basis of a casual conversation) in supposing that a previous darkening of the integument is usually or always a first stage in vitiligo (or leucoderma), there is probably some "law of nature" connecting the two states which demands more investigation than has yet been given to it even by Sir Samuel Wilks. I do not, therefore (as at present advised), feel disposed even on Sir Samuel Wilks's great authority to accept the dictum that in the true Addison's disease there shall absolutely *not* be found an instance of leucoderma, and that Addison's own illustration to the contrary is "a false representation."

Now as regards this classical and much controverted instance in Addison's own book. It is true that there was no post-mortem examination in that case as there delineated, but Sir Samuel Wilks has not adverted to a fact (which I noticed in my lecture) that Addison records this case side by side with another in which there was an examination, and where the capsules were found diseased, but in which no drawing could be procured; and certainly no doubt existed in Addison's mind at that time that the two cases were exactly parallel in every respect both as regards the skin and where the condition of the adrenals. Personally, I see no reason to doubt that Addison adhered to his judgment of this case, or to presume that he would in a second edition have relegated it to the category of "those doubtful instances which have done so much to retard the progress of the discovery." But of course it is open to Sir Samuel Wilks, or to anyone else, to doubt this case. In fact, I only alluded to the apparent discrepancy of opinion on this as "a point requiring to be more carefully dealt with."

As regards my own case, however, very briefly alluded to in the Transactions of the International Medical Congress (London, 1881) and afterwards published by Dr. McCall Anderson, I cannot quite submit to allow its relevancy to be brought into question on the grounds stated. It is true that I gave no extended description of the case, for I had no cognisance of it except at the one visit in consultation. But I affirm now with the utmost confidence: (1) that the disease was recognised during life both by myself and Dr. Maclaren of Glasgow as having all the constitutional symptoms of Addison's disease; (2) that this was confirmed later by Dr. McCall Anderson, who had at an earlier stage regarded the pigmentary changes as vitiliginous (as indeed they assuredly and typically were); and (3) that the examination after death made by the late Dr. Foulis of Glasgow in full knowledge of the diagnosis, and with every possible care as regards histological details revealed exactly the state of the adrenals regarded by Sir Samuel Wilks himself as characteristic of Addison's disease. I am not concerned at present with the other elements of doubt cast on Addison's observations, but I venture to continue in the belief that the "law of nature" alluded to by Sir Samuel Wilks as regards the continuity of the pigmentary change will have to submit to some further "apparent exceptions" before we can be considered as having quite done with the subject.

I am, Sirs, yours faithfully,

Penmaenmawr, N. Wales, July 30th, 1900. W. T. GAIRDNER.

"RODENT CANCER OF THE CORNEA."

To the Editors of THE LANCET.

SIRS,—The "rare chronic creeping ulcer of the cornea" spoken of by Mr. Nettleship does not differ from the condition described in my case simply because it is one and the same thing. A reference to my article will show that I used the terms "rodent ulcer" and "rodent cancer" as interchangeable. The reasons for my assuming malignancy in the ulcer were: (1) age of patients (nearly always late middle life); (2) the raised sinuous undermined edge of the ulcer and its chronic course; (3) nothing but destruction of the growing edge by the cautery appears to be able to arrest the progress of the malady; and (4) the one pathological examination of which I can find any record is that of Schmidt-Rimpler who describes appearances not inconsistent with malignancy. Perhaps the most suggestive points about Mr. Nettleship's "chronic creeping ulcer" are that lymphatic glands are not invaded; that the condition remains local; and, above all, that it does not recur after complete removal. These are cardinal features of the cutaneous rodent ulcer, which is nowadays admitted on all hands to be carcinomatous. They were present in my mind when I spoke of the condition as "rodent cancer of the cornea," although we must all admit that at present the etiology of the disease is a matter of speculation. Mr. Nettleship speaks of the "chronic creeping ulcer of the cornea" as "somewhat rare," whereas in my original article I called it "one of the rarest affections of the eye." My reasons were: (1) not a single identifiable case can I find either in periodical English literature or in the Transactions of the Ophthalmological Society of the United Kingdom; (2) during the last 10 years there appear to have been only five recorded cases—namely, four by Dufour (Société Français d'Ophtalmologie, May, 1897), and one by Schmidt-Rimpler (*Archiv für Augenheilkunde*, 1898); and (3) Vossius, in Giessen, saw three cases among 25,000 ophthalmic patients and Jany of Breslau one only among 66,000. On these grounds I based my conclusion that "rodent ulcer of the cornea" was an extremely rare affection. I am, Sirs, yours faithfully,

Welbeck-street, W., July 30th, 1900. SYDNEY STEPHENSON.

To the Editors of THE LANCET.

SIRS,—The assumption that Mr. Sydney Stephenson's interesting case of corneal rodent ulcer, published in THE LANCET of July 21st (p. 173), was cancerous must have been felt by many ophthalmic surgeons who read the account to be "not proven," and I note that Mr. Edward Nettleship has given expression to his doubts on the matter and asks for further proof. I am very interested in the point, as I have quite recently had under my care the healthy little and not quite three-year-old daughter of healthy parents, living in a most salubrious neighbouring seaside town, where the father is a medical man, with a state of things, as far as can be judged from the description and diagram, identically the same as in Mr. Stephenson's case, except that the upper part of the cornea was attacked. The condition is so rare, at least in these parts, it being the only case which I have encountered in a period of 11 years, that it was not until the ulcer went on steadily advancing in spite of all the usual remedies that I had the child put under chloroform, and after a thorough examination, which I could not make before, recognised the grave nature of the case, when careful scraping and the energetic single application of pure carbolic acid, spudding it well in under the epithelium of the advancing edge, quite arrested the disease and led to a complete cure without causing so much destruction of tissue as the actual or galvano-cautery would have done. Clinically this case appears to me exactly the same as Mr. Stephenson's. Would he in my three-year-old patient consider it cancerous? Was it the age of his patient that led him to adopt this view of its nature, or what? A critique of Ulcus Corneæ Rodens appeared in the *Ophthalmic Review* for April of this year.

I am, Sirs, yours faithfully,

Norwich, July 29th, 1900. S. JOHNSON TAYLOR.

THE CURATIVE TREATMENT OF MICROBIC DISEASE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 20th, 1890 (p. 1354), there appeared a letter of mine entitled "On Immunity from Infectious Disease." In this letter I proposed a method of treating infectious disease by (1) bleeding the patient in order to remove some of his vitiated blood and (2) replacing this blood by healthy blood obtained from an individual who had recovered from the same disease as the patient was suffering from. This method, as far as I am aware, has not been tried on the human subject. It has, however, been tried in Cape Colony on cattle suffering from rinderpest some two years ago and with great success. The treatment to be successful depends on a very thorough bleeding of the sick animal, in a full-grown ox to the extent of several (five or six) litres; on the other hand, the inoculating dose of defibrinated blood or serum from a recovered animal need not exceed from 20 to 30 cubic centimetres in the case of a "fortified" animal, or 100 cubic centimetres if the animal be not fortified. I think the method may be now tried on the human subject in pneumonia and other acute fevers where in the olden days bleeding was usually resorted to, with this addition, that immediately after the bleeding a dose of curative serum (anti-pneumonic, &c.) should be given, and to avoid all risks subcutaneously, instead of the method I proposed in my letter—viz., by transfusion. Perhaps in a case of typhus or typhoid fever, where the blood-giver is the human subject, direct transfusion of the "recovered" blood may be the safest procedure.

I am, Sirs, yours faithfully,

GEORGE CARRINGTON PURVIS, M.D., B.Sc. Edin.

Grahamstown, Cape Colony, July 7th, 1900.

"RUPTURE OF THE APPARENTLY HEALTHY ŒSOPHAGUS."

To the Editors of THE LANCET.

SIRS,—Dr. E. J. McWeeney's interesting paper on the above subject, published in THE LANCET of July 21st (p. 158), does not mention a table of 18 such cases which was appended to a paper by Dr. R. L. Bowles and myself sent in November, 1899, and read on March 27th of this year before the Royal Medical and Chirurgical Society and now published in its Transactions, p. 241. On analysing his table of 17 cases I find that Dr. McWeeney rejects two cases of Mr. Stanley Boyd's which we accepted. He tabulates one case rejected by Fitz which we did not include, but which perhaps it seems reasonable to accept. He does not include, as we did, Oppolzer's case, but mentions it with those of Williams, Bailey, and Heyfelder "as almost certainly belonging to this category." Two cases are in his tables in which an "ulcer" is described and are not included in our table. He does not mention three cases of Dr. S. West, of Dr. C. J. B. Williams, and of Guersent which are in our table He adds cases by Harrison and Wolf

and three (published since the compilation of our table) by himself, Heintze, and Lorrain Smith. Taking the 18 cases in our table and those added by him, five in all, and putting in those accepted by him but rejected by us (in two of these the word "ulcer" has led to confusion), the total number of all cases would seem to be about 25, a number sufficient to show, as Dr. Bowles and I contended in our paper, that this injury is not so rare as is commonly thought to be the case.

I am, Sirs, yours faithfully,

Half Moon-street, W., July 30th, 1900. G. R. TURNER.

"PADDLING IN THE SEA."

To the Editors of THE LANCET.

SIRS,—The letter of Mr. William Knight Treves on the above topic in THE LANCET of July 21st states that "for some reason or other paddling is very generally condemned by the medical profession." Presuming that Mr. Treves has good grounds for making such a statement—and I confess that I was not aware of such a prejudice—I cannot understand on what grounds paddling can be considered objectionable. The extensive sands of the Dee estuary are greatly resorted to by children of all ages for the express purpose of bathing and paddling, but principally for the latter delightful enjoyment. We have here, too, one of the largest preparatory boys' schools in England, the pupils of which school constantly go long paddles. I have therefore much pleasure in adding my testimony to that of Mr. Treves that paddling is not only delightful but beneficial to all children through the summer weather. My wish to help Mr. Treves in doing a "good turn to the children" is based not only on the experience gained as a medical man but also as a parent. It is usually the bad eating habits of children, not paddling, that "sends the blood to the head," whatever that picturesque phrase may mean. I am, Sirs, yours faithfully,

H. M. SPEECHLY.

Parkgate on the Cheshire Dee, July 20th, 1900.

MEDICAL SERVICE IN THE HIGHLANDS AND ISLANDS OF SCOTLAND.

To the Editors of THE LANCET.

SIRS,—Herewith I enclose copy of reply received by me last night from the Local Government Board in reference to the memorial from medical officers of the more remote parishes of the Highlands and islands which was recently presented to the Board. You will see by it that the Board favour the proposal but have not the power to insist upon the parish councils granting the privilege. While I have no doubt that some parish councils would grant their medical officers a paid substitute, yet I fear we shall have to wait for an alteration of the Local Government (Scotland) Act before we can hope to see the reform general.

I trust you will kindly publish the reply, and am, Sirs,

Yours faithfully,

JAS. F. D. MACARA,

Durness, Lairg, Sutherlandshire, July 27th, 1900. Medical Officer, Durness.

[COPY.]

Local Government Board, Edinburgh, July 25th, 1900.

SIR,—With reference to your letter dated 27th ultimo enclosing a memorial by the medical officers of the more remote parishes of the Highlands and islands of Scotland as to the difficulty experienced by them in obtaining an annual holiday, I am to say that this matter has received careful consideration from the Board. In reply I am to say that the Board desire to express their sympathy with the views expressed in the memorial, and having regard to the very special circumstances and conditions under which the duties of the memorialists have to be discharged are of opinion that it would be to the advantage of the public service that parish councils should grant an adequate holiday to their medical officers, defraying at the same time the cost of a substitute to act for the doctor during his absence. But, as the Board have often had occasion to point out, their powers in regard to the relation subsisting between parish councils and their medical officers are very limited, being derived solely through the medium of the grant in aid of medical relief to the conditions in connexion with the distribution of which parish councils are required to conform in order to participate. I am to add that the rules of the grant have been held to be stereotyped by the Local Government (Scotland) Act of 1889, so that, as will be seen, additional legislation would be necessary to give general effect to the views of the medical officers. The Board, however, direct me to say that they are prepared to do the best within their power—that is, they will offer no objection to the cost of substitute medical officers being ranked against the medical relief grant in the more remote parishes of the Highlands and islands of Scotland, provided that the local circumstances are such as are described in the memorial and provided care be taken that the parish council shall pay only for the services rendered by the substitute to the paupers and not for his services to the medical officers' private patients. The Board have forwarded a copy of this letter to Lord Lister.

I am, Sir, your obedient servant,

G. FALCONAR-STEWART, Secretary.

Dr. Macara, Durness, Lairg.

THE MEDICAL STAFF AND THE MANAGEMENT OF THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE.

To the Editors of THE LANCET.

SIRS,—In consequence of the appearance of an article in the *Times* of to-day we, the members of the honorary medical and surgical staff of the National Hospital for the Paralysed and Epileptic, Queen-square, now desire to address you on the crisis in the affairs of our hospital which has been brought about by the acts of the board of management during a number of years.

The relations between the medical staff and the board of management have shown increasing signs of strain for several years past, in proportion as the board has more and more relegated its functions and authority to the hands of a paid official, Mr. Burford Rawlings, who, from the position which he originally occupied as secretary, has been advanced to the dignity of "secretary and general director." Those practically acquainted with hospital affairs will scarcely need to be told that the effect of such an appointment is that although the management of the hospital may be nominally directed by a board the institution is practically, to a great and dangerous extent, in the hands of one man. That the autocracy of the office referred to should be as complete as possible it is enacted in the rules of the hospital that no member of the medical staff shall be allowed to have a seat on the board. The "secretary and general director" is thus relieved of any inconvenience which might possibly be occasioned by the presence on the board of persons professionally acquainted with the work and necessities of a medical institution and able to supply essential information and counsel.

It is not surprising, therefore, that for a number of years the medical staff have found that the administration of the hospital was becoming more and more unsatisfactory. Ten years ago, with the view of remedying this state of things, the medical staff suggested to the board of management that two of the medical officers should be annually elected members of the board (12 members) as their representatives. This was refused and various substitutes were proposed by the board which have proved failures owing to acts of the board. The first of these substitute arrangements was summarily terminated in 1893 by a decision of the board of management, no reason being assigned. The last of these arrangements came to an end in 1899 in consequence of a breach of faith on the part of the board of management. Since then the medical staff have renewed their claim for direct representation, which the board have persistently refused, and as a result a state of acute dissension between the two bodies has existed since the early part of last year. In July, 1899, the chairman of the Distribution Committee of the Hospital Sunday Fund warned the secretary and general director that unless the want of harmony ceased the customary grant would not be renewed in the following (this) year, at the same time expressing the opinion that the medical staff should be directly represented on the board of management. He also instructed the secretary director to communicate these observations of the committee to the board of management. We must here observe that the secretary director, Mr. Burford Rawlings, in reporting to his board did not communicate the whole of the instructions he had received from the chairman of the Sunday Fund Committee, but informed them that the chairman (Sir Sydney Waterlow) had "confined his observations to an expression of regret that perfect harmony did not exist between the board and the staff and the expression of the hope that this state of things would have passed away before next year."

Between the meeting of the Sunday Fund Committee last year and that held on July 19th the medical staff, after further fruitless negotiations with the board of management, determined to inform the governors of the hospital not only

of the defects of its constitution but also of certain administrative evils which had resulted therefrom. To this end the medical staff issued to those governors whose names and addresses could be discovered by them a statement and report of the condition of the affairs of the hospital. This report we enclose together with other documents. It should be noted that an application by the medical staff for a copy of the official list of the names and addresses of the governors was refused by the board of management. The next step was the appointment by the board of a sub-committee consisting of three of their own members to investigate the grave defects to which their attention had been called and for which they were responsible. The medical staff naturally at once repudiated such an unsatisfactory inquiry and urged upon the governors that any committee of investigation should be an independent one and not appointed by the body whose acts were called in question.

The final stage of this dispute was reached at the recent meeting of the Distribution Committee of the Hospital Sunday Fund. The Sunday Fund Committee, bearing in mind their instructions to the board of management of last year, issued this year a request to the board and medical staff respectively to send representatives to their meeting on July 19th.

After hearing both sides the Distribution Committee of the Hospital Sunday Fund adopted the following resolution for submission to their council:—

> In consequence of the serious dissensions between the staff and the board of management at the National Hospital for the Paralysed and Epileptic, Queen-square, your committee held a conference at which both were fully represented. After a long discussion it was decided that no award could be recommended until the existing differences had been satisfactorily arranged.

In conclusion, we desire only to reaffirm our view that the affairs of the hospital need a searching inquiry and its constitution thorough reform. We are unanimous in our resolve to put an end to the evils of the present system of administration. We are, Sirs, yours obediently,

J. HUGHLINGS JACKSON, M.D. St. And., F.R.C.P. Lond., F.R.S.,
THOMAS BUZZARD, M.D., F.R.C.P. Lond.,
Consulting Physicians to the Hospital.
R. BRUDENELL CARTER, F.R.C.S. Eng.,
Consulting Ophthalmic Surgeon
H. CHARLTON BASTIAN, M.D., F.R.C.P. Lond., F.R.S.,
W. R. GOWERS, M.D., F.R.C.P. Lond., F.R.S.,
DAVID FERRIER, M.D. Edin., F.R.C.P. Lond., F.R.S.,
J. A. ORMEROD, M.D. Oxon, F.R.C.P. Lond.,
Physicians to In-patients.
CHARLES E. BEEVOR, M.D., F.R.C.P. Lond.,
HOWARD H. TOOTH, M.D., F.R.C.P. Lond.,
JAMES TAYLOR, M.D. Edin., F.R.C.P. Lond.,
J. S. RISIEN RUSSELL, M.D Edin., F.R.C.P. Lond.,
Physicians to Out-patients.
W. ALDREN TURNER, M.D. Edin., F.R.C.P. Lond.,
FREDERICK E. BATTEN, M.D. Cantab., M.R.C.P. Lond.,
Assistant Physicians.
FELIX SEMON, M.D. Berlin, F.R.C.P. Lond.,
Physician for Diseases of the Throat.
VICTOR HORSLEY, F.R.C.S. Eng., F.R.S.,
CHARLES A. BALLANCE, F.R.C.S. Eng.,
Surgeons.
R. MARCUS GUNN, F.R.C.S. Eng.,
Ophthalmic Surgeon.
A. E. CUMBERBATCH, F.R.C.S. Eng.,
Aural Surgeon.

(The names of absent members have been added by authority.)

July 27th, 1900.

"THE APPOINTMENT OF SPECIAL MEDICAL OFFICERS FOR THE CERTIFICATION OF LUNATICS."

To the Editors of THE LANCET.

SIRS,—What Mr. Polhill Turner proposes in THE LANCET of July 28th is identical with what I proposed in a short pamphlet entitled "Proposals for the Amendment of the Laws relating to Lunatics and Habitual Drunkards," published in 1885. Many, if not all, of the anomalies now connected with the process of certification of lunatics would be obviated by the adoption of some such plan, and much benefit will accrue, not only to the public, but to the profession, if such a plan were to receive your powerful advocacy. Only those whose fate it is to have to do with lunacy certificates, both in their inception and in their completion, know how gladly a simplification of the process such as that proposed would be welcomed.

I am, Sirs, yours faithfully,

Hendon, July 31st, 1900. W. H. KESTEVEN.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University College, Liverpool: The Work of the Medical Faculty.

THE medical faculty, which may be regarded as the foundation-stone of University College, continues to flourish. Professor A. M. Paterson, the Dean of the Faculty, in his recently-issued report for the past year remarked on steady progress in all departments. The number of students attending classes during the winter session of 1899-1900 (excluding those taking out hospital practice) was 194. In 1897-98 and 1898-99 the numbers were 169 and 188 respectively. There were 85 new entries, including 60 medical, 13 dental, and 12 entering for special courses. In the previous winter session there were 88 new entries—54 medical, 19 dental, and 15 for special courses. During the present summer session the total numbers have been 163, including 10 new entries and 16 for special courses. Last summer the total reached 144, including 12 new entries and five for special courses. These figures represent the largest numbers in the history of the medical school. The increase was mainly due to students taking special courses or parts of their medical curriculum. Professor Paterson elaborates the subject of buildings. Last year the plans of the new building were devised and passed. The scheme was divided for building purposes into three sections, which was necessitated through lack of funds. The first section, comprising an anatomical museum and dissecting-room, is now being erected. The second section will include, in addition to the main staircase, the laboratories for surgery and the lecture theatres. The third section, which will complete the block, will contain laboratories and smaller rooms necessary for teaching, investigation, and administration in the several departments of the school. Professor Paterson regrets that the surgical section of the building has not already been begun, as the completion of the old block would be expedited by the erection of that section. The estimated cost of the three sections is £30,000, towards which promises of £14 000 have been received. As each section of the building is estimated to cost about £10,000, a start will be made with the second section when the requisite sum of £6000 has been guaranteed.

Woolton Convalescent Institution.

The twenty-sixth annual meeting of the Woolton Convalescent Institution was held on July 21st. The institution is largely self-supporting; payments made on behalf of patients amounted last year to £1729 4*s*., whilst the total receipts realised £4701 5*s*. 4*d*. Subscriptions amounted to £944 8*s*. 6*d*. The Hospital Sunday Fund contributed £315, the proceeds of the city ball amounted to £159 0*s*. 8*d*., and during the year donations had been received amounting to £415 4*s*. The number of patients received into the institution was 2661, which was six short of the previous year, but showed 25 per cent. above the average for the past 10 years. The accounts showed an increase in the debit balance from £63 to £354, which was due to necessary alterations in the institution. The number of special subscriptions had increased and Mr. T. S. Timmis had endowed a free bed, bringing the number of free beds up to 20. The popularity of the institution is evidenced by the fact of the number of applicants for admission. In the year 1878 the number of patients was 638 and the annual subscriptions were £110, as compared with 2661 patients and £944 recorded for the past year. The grounds of the institution have been considerably improved at an expense of £1206, and the committee have spared no effort to make the institution comfortable and attractive. The Council in their report referred with great regret to the death of Sir Henry Tate, Bart., who had closely connected himself with the institution for many years, having been the honorary treasurer

in its early days and a liberal donor to its funds. A number of seats for the grounds were presented by the Lord Mayor, Sir William Tate, Bart., and Mr. S. S. Bacon. Complimentary references to the benefits of the institution were made by the Lord Mayor, Monsignor Nugent, Sir Henry Tate, and others.

Hospital Saturday and Sunday Funds: Distribution of Grants to the Charities.

The joint committees of the Hospital Sunday and Hospital Saturday Funds distributed the following amounts among the local charities:—Royal Infirmary, £2860; Royal Southern Hospital, £1950; Northern Hospital, £1690; Stanley Hospital, £910; Liverpool dispensaries, £780; Queen Victoria District Nursing Association, £780; Infirmary for Children, £780; Eye and Ear Infirmary, £520; Consumption Hospital, £455. A sum of £2080 was also distributed among minor charities, making a grand total of £12,805.

July 31st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Death of James Rodger, M.A., M.D. Aberd., of Aberdeen.

LAST week Aberdeen lost one of its best known medical practitioners, Dr. James Roger. The deceased was born in 1841 in Aberdeen, where his father owned the Gilcomston tanworks in Rodger's-walk. Dr. Rodger had a distinguished university career. In 1865 he graduated M B., C.M., both with highest honours; and from 1865 to 1867 and from 1868 to 1871 he was demonstrator of anatomy at Aberdeen University under the late Professor Sir John Struthers. During the interval (in 1867 and 1868) he studied at Paris, Berlin, and Vienna. He volunteered his professional services during the Franco-Prussian war, in recognition of which (including the organisation of the Saarbrucken hospital) he received from William I. of Germany the war medal for non-combatants, and on his return to Scotland in 1871 he was awarded a money gratuity by the International Society for Aid to the Sick and Wounded in War. He was physician to Aberdeen General Dispensary from 1870 to 1876, and from 1869 for about 17 years he was pathologist to Aberdeen Royal Infirmary, of which he was, further, assistant physician from 1886 to 1897, being thereafter honorary physician. In 1874 he was appointed one of the examiners in anatomy, pathology, and medicine at Aberdeen University. He also held various other public appointments in his native city, such as physician to Robert Gordon's College; secretary, treasurer, and president in succession of the Aberdeen Medico-Chirurgical Society; and surgeon-lieutenant-colonel of the 1st Aberdeen Volunteer Artillery. He had a large private practice, consultant and otherwise, and though somewhat abrupt in manner, his geniality, general cleverness, and professional ability were widely recognised. Dr. Rodger married a daughter of the late John Hill Burton, historiographer royal for Scotland, author of "The Scot Abroad," "The Book Hunter," &c.; and one of the last acts of his life was to offer as gifts to Marischal College, Aberdeen Free Library, Aberdeen Art Gallery, &c., replicas of a noted bronze bust of his father-in-law.

July 31st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Water Supply.

LITTLE is being done among the learned societies of Paris just now, for all the active members are reserving their most interesting communications for the great International Congress of Medicine which is on the point of being opened and which absorbs everything. The Academy of Medicine is the only one where there has been an important discussion, and in this case the subject considered was one of general interest at the present time, being no other than the state of the Paris water-supply, which attracts attention regularly every year during the hot weather. The temperature has now become milder, but it was exceptionally high during the last fortnight, on one of the days of which there was the highest temperature of the century in Paris. The consumption of water naturally increased at once and even commenced to exceed the anticipations of the engineers, who announced last spring that precautions had been taken and that in consequence of the opening up of new sources of supply and the construction of new filtering beds the Parisians would never again be in want of water, even with the most extravagant waste and with the increase of the population during the Exhibition. The quantity provided for each inhabitant of Paris is, in fact, 230 cubic metres (50,620 gallons). Nevertheless, it soon became insufficient, as had to be admitted by the water company itself, which promptly posted up throughout Paris the notices with which it favours the public every year, warning Parisians to limit their consumption in order to prevent an early failure of the supply. It is undeniable that owing to the hot weather there is an excessive consumption of water. For the purpose of saving a penny-worth of ice, people do not hesitate to let the water run for hours in order that it may be cool for drinking. The first water which comes after the turning of the tap is in fact quite hot, because the service pipes are generally outside the houses and are heated all day by the sun. Ineffectual attempts have been made to compel the use of water taps which remain open only so long as a hand is on them. Small metal nuts with an internal screw are sold which enable the taps to be kept always open. But from what has just been said it will be seen that with the usual rate of flow from a tap even if it was open all day long only a small portion of the allowance of each inhabitant would pass through it. It is the water company itself which is the real offender. If the spring water were reserved solely for human consumption the quantity supplied would be ten times more than the population required, but in actual fact the water company uses this spring water for all purposes, for lifts, street-watering, &c., in all the high-lying districts where the Seine water cannot be supplied under sufficient pressure by means of the company's pumping machinery. The remedy would be to use more powerful pumps and to fit up all the houses with a double set of service pipes, one for spring water and one for Seine water, but the company prefers not to incur the expense which would fall upon it alone. By its agreement with the city of Paris the water company is not required to provide pipes, mains, or machinery, the water being supplied to the company free of charge by the city, which undertakes the collecting of it and the construction of the means of conveyance. It is easy to understand that from motives of economy the company prefers to make general use of spring water which is delivered naturally at a sufficient pressure, rather than to erect costly machinery for raising Seine water to the requisite height and to provide a separate service for it in each house. This is the real difficulty of the question. At last the Academy of Medicine has intervened. The company having stopped the supply of water during the night in order to allow the reservoirs to become full everybody complained, especially the fire brigade—the latter on the ground that fires generally broke out at night and that the pressure of the water was insufficient for the fire engines. M. Laveran and M. Henriot opened a discussion in the Academy on this subject, and proposed the following motion which was passed unanimously:—

> The Academy of Medicine feels itself compelled to call the attention of the public authorities to the state of the Paris water-supply which is at the present time quite inadequate. The Seine water not being at sufficient pressure is in certain localities replaced by spring water being used for washing purposes. If there was a proper supply of Seine water there would be no deficiency of spring water for human consumption.

The Academy also passed the following motion:—

> A double service for spring water and for Seine water ought to be established everywhere, so that they may be kept quite separate from one another.

The Prohibition of Spitting.

Some days ago announcements to the following effect, printed on small white bills (the official colour), were to be seen on the walls of the public buildings everywhere in Paris:—

> NOTICE.—In the interests of public health and with the view of checking the spread of tuberculosis persons are requested not to spit on the ground ("*par terre*").

This was the result of a resolution of the municipal council and of a discussion on a report presented by M. Fortin last March. As might be expected some journals complained, saying that spitting in omnibuses, tramcars, and railway carriages had been already prohibited, and asking where people might spit if they must not spit on the ground. The

object of the notice, however, was only to discourage spitting on the pavement ("*sur les trottoirs*") and not in the roadway.

July 31st.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Diseases of the Philippines.

AN interesting paper was read recently before the Southern Idaho Medical Association by Dr. W. D. Springer of Boise in that State, who served as surgeon of the Idaho Regiment in the Philippines. He said that among the troops malaria, small-pox, typhoid fever, dysentery, tropical diarrhœa, intestinal parasites, and skin diseases were the most common maladies. Typhoid fever prevailed on an extensive scale, but amœbic dysentery was the most frequent and fatal disease. A complaint known as "Manila itch," "Dhobie itch," or "Filipino itch" was the most common of the skin affections. This is of parasitic origin and peculiar to the tropics. It spreads very rapidly during the hot, damp season. It attacks first the perineal region and the axilla. After the acute stage is over and the inflammation is somewhat subsided scales rub off and the inflammation gets down about the feet, where it spreads. The burning and itching are much worse at night, and cause much suffering. The patient unconsciously scratches the part affected, and this in many cases causes boils. The regions occupied by the disease always remain pigmented. This trouble was almost universal among the troops. Small-pox, Dr. Springer stated, prevailed all the year in Luzon and the troops suffered severely from it. The report of the Surgeon-General attributed over 200 deaths to this cause. Dr. Springer, however, drew attention to the fact that where vaccination was carefully practised and reliable lymph was used small-pox was absent, and he was of opinion that both its prevalence and its mortality were owing to the carelessness shown in performing the operation and the inferior quality of the vaccine lymph.

Public Baths in the State of New York.

There has been some difference of opinion recently as to who is entitled to the chief credit for the establishment of free public baths in the State of New York. This honour has been claimed in several journals by the Hon. Goodwin Brown. The *Medical Record*, however, took up the cudgels for Dr. Simon Baruch and proved fairly conclusively that this good work was first commenced on his suggestion. The *New York Herald* of October 25th, 1891, referring to the opening of some baths built by funds supplied by Baron Hirsch, says, "These rain baths are something entirely new for this country. Attention was first called to this system of baths in this country by Dr. Simon Baruch. Dr. Baruch spent six months in Europe studying the baths of all foreign nations. On his return he brought the subject before the Academy of Medicine and headed the rapidly-growing movement for public baths." The report of the committee on public baths appointed by the Mayor of New York, transmitted to the Legislature on March 25th, 1897, was that out of 480 houses visited only 17 had baths and only three houses of each 100 had bath-rooms and that there were only three public baths in the city of New York. The Bill, which became law in 1895 and for which the Hon. Goodwin Brown was mainly responsible, reads as follows: "All cities of the first and second class shall establish and maintain such number of free public baths as the local board of health may deem to be necessary." This is the first general legislation on the subject ever enacted in the United States and the first bath erected under its provisions was opened in Buffalo in January, 1897. It has a capacity of 1000 baths daily and cost $8000 (£1600). In Rochester a bath has been erected to all intents and purposes on similar lines to that of Buffalo at a cost of $5000 (£1000). In Albany the money has been appropriated, and plans prepared, for a bath in that town the cost of which will be $22,000 (£4400). In Greater New York the first public bath is nearing completion and is likely to be opened in the course of a month or so. It is situated on the water front in a crowded part of the city, and will cost $100,000 (£20,000). It will have a capacity of 3000 baths per day—one-third each for women, men, and boys The United States is very many years behind most European countries so far as free public baths are concerned. The following cities contain public baths:—Boston, Chicago, Yonkers, New York, Brookline (Mass.), Providence, Philadelphia, Worcester, Buffalo, and Rochester. In a country, therefore, which contains upwards of 80,000,000 people, there are only about a dozen cities that provide bathing facilities. The health authorities seem to be becoming impressed with this lack and probably in the course of a few years the United States will be as well equipped with public baths as are countries on the other side of the Atlantic.

The Disinfection of New York.

An anti-germ crusade has recently been carried on by the active Board of Health in this city. An appropriation of $20,000 (£4000) was recently made to the Board of Health for the purpose of cleansing the unsavoury districts of New York. Probably the occurrences in the Chinese quarter of San Francisco impelled the authorities of New York to set their house in order and to run no risk of the plague or any other infectious disease gaining a foothold there. At any rate, be the cause of the action what it may, the proceeding can have none but good effects, and the activity of the New York Board of Health is a useful object-lesson to such bodies everywhere. The sanitary condition of New York, as proved by its vital statistics, has improved to a wonderful degree within the past few years. For this the chief credit is due to the Board of Health.

July 14th.

Obituary.

JOHN STUART STEVENSON, M.R.C.S. ENG., L.R.C.P. LOND.,

CAPTAIN, INDIAN MEDICAL SERVICE.

In THE LANCET of July 28th we announced the sudden death of Captain J. S. Stevenson of the Indian Medical Service. A further telegraphic message has now conveyed the news that this promising young officer fell a victim to heat apoplexy at Lucknow on Friday, July 20th.

John Stuart Stevenson was born at Benares on August 24th, 1872, where his father was stationed as the medical officer of a battery of Royal Artillery. He was educated at St. George's College, Croydon, matriculated at the London University, was entered as a student at St. Bartholomew's Hospital, and became a Member of the Royal College of Surgeons of England and a Licentiate of the Royal College of Physicians of London in 1895. In the spring of 1896 he took the fifth place among 17 selected candidates for the Indian Medical Service, and passing through the Army Medical School in the summer session of that year was duly gazetted as a Surgeon-Lieutenant on July 29th. Within three months of his arrival in India he was appointed to do duty on the railway as an examiner to prevent the spread of the plague in the north of India. Few men of his years had such opportunities of studying this disease, for he was subsequently sent to Bangalore on plague duty, and last year he was sent to Mauritius as "special plague officer," a position which he occupied with great credit for about a year. While at Mauritius he volunteered for active service in South Africa, but his services could not be spared. When the plague was stamped out in Mauritius and he returned to India he was appointed to the important post of deputy-sanitary-commissioner of the North-West Provinces—a post which he had held for a brief period when he so suddenly passed away. Captain Stevenson was a general favourite in society and won considerable reputation while in the Mauritius for the careful way in which he carried out the very important charge committed to him. He served on the North-West Frontier of India in 1897-98, when he was with the Tirah force and in the operations in the Mamund country, for which services he received the medal and clasp. He was duly promoted to be a captain on July 29th, 1899, and was considered to be one of the most rising young officers of the service. He was the only son of Surgeon-General W. F. Stevenson, now with Lord Roberts in the Transvaal, who at the opening of the war was taken from his appointment of professor of surgery in the Army Medical School, Netley, and sent out to South Africa as principal medical officer on the line of communications in Cape Colony and consulting surgeon to the forces. To him who in the midst of an arduous campaign has now to face this great sorrow and to the other members of the family we offer our heartfelt sympathy.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT IPSWICH.

THE sixty-eighth meeting of the British Medical Association was opened at Ipswich on Tuesday, July 31st, under the presidency of Dr. William Alfred Elliston, senior surgeon to the East Suffolk and Ipswich Hospital. This is the first occasion upon which the Association has met at Ipswich.

Ipswich, although it cannot lay claim to the ancient history and natural beauties of Edinburgh or to the naval and military importance of Portsmouth, has nevertheless peculiar interests of its own. It will always be remembered as being the birth-place of Cardinal Wolsey, of whose connexion with his native town a sad memorial remains in the crumbling Wolsey Gateway—all that is left of the demolished college with which Wolsey intended to endow Ipswich. Less fortunate than its founder's other great educational establishment at Oxford, it fell into the same rapacious hands which so nearly destroyed St. Bartholomew's Hospital.

The streets of Ipswich are narrow, yet they are singularly clean and well kept, while there still remain many beautiful examples of old domestic architecture. Perhaps the most notable is the "Ancient House," dating from 1567, though the ornamentation, we should fancy, was somewhat later, as it is distinctly Jacobean in style. Another striking building is the Neptune Inn. Christchurch Mansion, a fine old Elizabethan house, together with its park, now belongs to the town.

The systems of water-supply and drainage of Ipswich are worthy of note. The water is derived from chalk at some considerable depth and hence in quality is similar to that of the Kent Company's wells. At present there is practically little adopted in the way of actual purification of the sewage. What is done is that the sewage is screened at the outfall and after some attempt at precipitation is allowed to flow into the river Orwell without further treatment. The district, of course, is very flat and somewhat unfavourable to satisfactory sewage disposal. Indeed, the Stoke and Marsh districts are too low for connexion with the main drainage system which depends upon gravitation. Consequently recourse is had to the Shone pneumatic system which is applied in conjunction with the Hermite process of treating sewage with electrolysed salt water. The salt water of the estuary of the Orwell affords an abundant supply of material for this purpose. The streets of the town appear to be well kept and the reproach of being "smelly" which was at one time levelled against Ipswich and its thoroughfares has been removed.

Dr. William Alfred Elliston, the President-Elect, gave a dinner on Monday evening, July 30th, to the members of Council, the presidents of sections, and others. The following were among the guests: the Lord Bishop of Norwich, the Lord Lieutenant of Suffolk, the High Sheriff of Suffolk, the Mayor of Ipswich, Dr. Dawson Williams (the Editor of the *British Medical Journal*), and Dr. H. P. Cholmeley (representing THE LANCET). There were only two toasts, that of "Her Majesty the Queen" and that of "The Colonial Members." To the latter Professor T. G. Roddick of Montreal, whose name had been coupled with the toast, replied. On the afternoon of the same day Mrs. Elliston received, at Stoke Hall, the members of the Local Committees and such members of the Association as had arrived in Ipswich.

The space devoted to the Annual Museum was somewhat scattered, though this fact afforded an excellent opportunity of dividing the exhibits into distinct classes. What is known as the Public Hall in Westgate-street was set apart for the display of food and food products, drugs and mineral waters, while the old museum rooms close by were devoted to the exhibition of surgical instruments, hospital appliances, aseptic furniture, &c. The Public Hall admitted of a more artistic arrangement of the exhibitors' stalls than was possible in the Drill Hall at Portsmouth last year or at Edinburgh in the previous year. The exhibitors, indeed, must have found it a welcome change to have been able to place their exhibits in a structure having no glass roof with the hot sun's rays playing upon it and possessing some pretence at design instead of that rectangular precision of the average drill hall, which has been provided on previous occasions.

From the point of view of structure the Public Hall in Westgate-street may be regarded as resembling the Queen's Hall in London, having a gallery and orchestra-platform. At intervals a selection of music was provided. Despite the ample space afforded the Exhibition was decidedly on a small scale when compared with those of previous years. One very notable and commendable advance in the direction of accommodation was the provision of seats between the rows for the visitors and a smoking lounge. The stalls were on the whole tastefully arranged and were practically ready for inspection on Tuesday, though the attendance on that day was somewhat meagre. We may repeat what we said on the occasion of last year's meeting that the Organising Committee might make this feature of the annual meeting more attractive and interesting to the members by including amongst the exhibits a selection of a really scientific and instructive character. At present it may be said that demonstrations of the x rays are the only things laying claim to this description.

In another column will be found the first contribution of a special account of the exhibits at the annual museum, for which purpose the order of treatment adopted in previous years will be retained as being on the whole the most convenient. This is as follows:—1. Drugs. 2. Foods and food products. 3. Sanitary appliances, disinfectants, &c. 4. Surgical instruments and appliances. 5. Mineral waters and beverages. 6. Publications. 7. Miscellaneous.

St. Mary-le-Tower was appointed as the church for the opening service, and at 11 A.M. on Tuesday the edifice was filled with a congregation composed of the members of the Association and their friends, amongst whom were a great number of ladies. The order of service was appropriate to the occasion and the Lord Bishop of Norwich, the Right Rev. John Sheepshanks, delivered a somewhat long discourse, in which the peroration was the most impressive feature. The text was the oft used one from the uncanonical book of Ecclesiasticus (chap. xxxviii. verses 13 *et seq.*):

"Honour the physician with the honour due unto him, for the use ye may have of him: for the Lord hath created him.
For of the Most High cometh healing, and he shall receive honour of the king.
The skill of the physician shall lift up his head, and in the sight of great men he shall be in admiration.
The Lord hath created medicines out of the earth, and he that is wise shall not abhor them."

The musical service was admirably rendered as it was tastefully appointed. The offertory was, as on previous occasions, devoted to the British Medical Benevolent Fund and we learn that the proceeds amounted to 20 guineas.

The corporation of Ipswich was represented by the mayor, aldermen, and councillors who were present in state attended by the sword and mace bearers. The service formed a fitting and imposing prelude to the proceedings of the Association.

On the afternoon of Tuesday, July 31st, Mr. D. Ford Goddard, M.P., gave a garden party to the members of the Association and their friends at Oak-hill. Many of the leading townspeople and local residents were invited to meet the Association, and in all about 500 were present. The weather was beautifully fine, music was provided by the Ipswich Town Band, and a most enjoyable afternoon was spent.

In many ways the minds of all of us have been for nearly a year past exercised with affairs in South Africa. It therefore comes as a somewhat remarkable coincidence that a resolution which may have the most far-reaching effects upon the medical profession should have been carried at the second general meeting (held on August 1st), at the instance of a member from Cape Town—namely, Dr. C. F. K. Murray, President of the Cape Town Branch of the British Medical Association, who proposed the following motion:—

That this meeting resolves that the Council be requested to issue a circular to all branches of this Association inviting them to express an opinion and to submit proposals on the question of the "wage-limit" as applied to clubs, provident dispensaries, and societies, &c., with a view to suggesting a reasonable and fair working basis; furthermore, that it be an instruction to the Council to report and advise this Association thereon at its next annual meeting.

We have in these columns so frequently and so earnestly insisted upon the necessity of the wage-limit that it is a great pleasure to us to be able to record the passing of this resolution, and we congratulate both Dr. Murray and the Association upon the fact.

Another most important decision arrived at at the same meeting was that agreeing to the appointment of a committee consisting of 24 members to consider and report upon the best means of re-organising the constitution of the Association, 12 members being nominated by the Council and 12 by the general meeting—the whole 24 members being eventually elected by the members assembled in general meeting. It was understood that the Council would submit the names of their nominees on the following day (Thursday) at the general meeting and that the full committee would likewise be settled on the same day.

As it is proposed that the committee should report to the branches by Feb. 1st next, in order to present a complete scheme of re-organisation to the annual meeting at Cheltenham, there can be no question that much has to be accomplished in the small time at the disposal of the committee, and there can be few who are sanguine enough to expect the committee to attain its object and present a workable scheme within the period suggested. True, there is the now abandoned scheme of constitution presented by the Council to, and rejected by, the Exeter Hall meeting which should at least form a very substantial nucleus; but every well-wisher of the Association, and none more heartily than ourselves, must fervently hope that no attempt will be made to pass a hurriedly prepared scheme which may in the end not attain the desired result.

At the invitation of the Gloucester Branch it has been decided to hold the next annual meeting of the Association at Cheltenham, and Dr. G. B. Ferguson has been appointed President-elect.

THE GENERAL MEETINGS.

THE FIRST GENERAL MEETING.

The first general meeting of the Association was held in the Central Hall of the Higher Grade School at 3 P.M. on Tuesday, July 31st, the Council being well represented on the platform, and some 150 members of the Association being present in the body of the hall.

Mr. WARD COUSINS, the retiring President, took the chair, and moved that the minutes of the last annual meeting be confirmed, which was agreed to.

The CHAIRMAN said that his first duty was a very sad one. Everyone present had no doubt heard of the very sudden death of the Duke of Saxe-Coburg Gotha, better known to us as the Duke of Edinburgh. He was sure that everyone present would sincerely join with him in the vote of sympathy which he was about to propose. The vote was couched in the following terms:—

That this meeting of the members of the British Medical Association, assembled at Ipswich, desire to express their deep sympathy with Her Most Gracious Majesty the Queen, H.R.H. the Duchess of Edinburgh, and all the members of the Royal Family at the sad and sudden death of H.R.H. the Duke of Edinburgh and Saxe-Coburg.

Mr. Ward Cousins then vacated the chair in favour of Dr. William Alfred Elliston, Senior Surgeon to the East Suffolk and Ipswich Hospital and President for 1900–1901.

Dr. ELLISTON took the chair amidst applause, and moved that His Royal Highness the Prince of Wales, K.G., Hon. F.R.C.P., Hon. F.R.C.S., be elected an honorary member of the Association. He said that His Royal Highness had kindly intimated that he would be pleased to become an honorary member.

Professor RODDICK of Montreal seconded the motion, and expressed the hope that at some future meeting the Prince would honour them with his company.

The motion was carried unanimously.

Sir WALTER FOSTER, M.P., moved a vote of thanks to the retiring President, Mr. Ward Cousins, for so ably presiding over the Association during the past 12 months, which was seconded by Dr. C. HOLMAN and agreed to unanimously and suitably acknowledged by Mr. WARD COUSINS.

The President of the Council, Dr. JOHN ROBERTS THOMSON, then moved that the annual report and statement of accounts be adopted. He said that he knew that the moving of the adoption of the report was considered an opportunity for members to speak upon various points and, therefore, he would not detain the meeting with any remarks of his own.

Mr. ANDREW CLARK, the treasurer of the Association, seconded the motion in a few words.

The first member to rise to speak was Lieutenant-Colonel INCE, I.M.S., who expressed dissatisfaction with the action of the Council on certain points but congratulated the editor upon the Journal of the Association.

The report contained among other matters a paragraph about the Coventry Provident Dispensary wherein it was noted that

At the last annual meeting the Council was requested to ascertain whether any of the present medical officers of the Coventry Provident Dispensary were members of the Association and if so that they should be called upon to explain why they still continued to give their services to that institution. In their report these gentlemen claimed to have obtained several reforms in the last few years and hoped to obtain more, and that further, many of the statements made with regard to the institution were inaccurate.

The following motion was passed:—

Resolved: That the Council is glad that the medical officers of the Coventry Provident Dispensary are still endeavouring to get the rules altered and strongly recommends them to continue their efforts to obtain a wage limit as expressed in their letter of Oct. 8th.

In reference to the above Mr. G. BROWN considered that some stronger steps should be taken in the matter of the medical officers of the Coventry Dispensary, who should be called upon either to mend their ways or to cease being members of the Association.

Dr. R. SAUNDBY said that he could not see why the Coventry Dispensary should be specially singled out for r probation. He held no special brief for the Coventry Dispensary, and it was true that it had no wage-limit, but neither had the friendly societies any wage-limit. Gentlemen who held the posts of medical officers to friendly societies came down here and howled (uproar and loud cries of "Withdraw") at the Coventry Dispensary because it had no wage-limit, which was not fair. Dr. Saundby was

"Annals of Ipswich," by Nathaniel Bacon; and "Old much interrupted in the course of his remarks, and the Chairman appealed for order.

Dr. E. PHILLIPS of Coventry said that the Coventry Dispensary was condemned in 1892, when 25,000 persons belonged to it. The medical officers of the dispensary said that since 1892 they had been endeavouring to obtain reforms in the matter of the wage-limit, and apparently they were still endeavouring. The dispensary was condemned alike by THE LANCET and the *British Medical Journal*, and its advertisements were refused insertion by both these journals.

Dr. F. M. POPE of Leicester said that they must either let these medical officers alone or else expel them. There was no middle course. A motion for expulsion in a meeting like that, always raised the worst possible feelings. He was sure that they did not desire to do that. Even supposing a medical man started a practice at penny fees he did not believe the Association would be willing to expel him.

Mr. R. B. ANDERSON took up the subject of the Council's report on the question of the Midwives Bill. The terms of the report did not satisfy him. He therefore proposed a very lengthy rider to the section of the report in question, upon which a long, and in many ways irrelevant, discussion arose, the principal speakers being Dr. BRASSEY BRIERLEY, who harked back to the Coventry Dispensary question, Dr. J. HADDON, Dr. A. COX of Gateshead, who seconded the addition of Mr. Anderson's rider and said that THE LANCET *plébiscite* showed plainly that the feeling of the profession was against the Midwives Bill, and Mr. D. O'SULLIVAN. Finally Mr. VICTOR HORSLEY pointed out the danger of correcting one inaccuracy by another inaccuracy, and portions of Mr. Anderson's rider were undoubtedly inaccurate.

Mr. ANDERSON said that as the accuracy of his statement had been called in question he would withdraw his rider.

Amid cries of "Vote" the whole of the rider was eventually withdrawn.

Another paragraph in the report referred to the new Articles of Association in the following terms:—

> Certain difficulties and legal questions on the Articles of Association as adopted when the Association was first incorporated in 1874, which articles had been mainly drawn on the basis of the regulations of the unincorporated Association, having arisen, the Council consulted eminent counsel on the matter, and was advised to adopt amended regulations, as the Association had outgrown the old constitution. New regulations and articles were prepared by your Council and submitted to a special meeting of the Association held in London, on July 18th, but the resolution was not carried by the requisite majority.

A discursive conversation—it could not with justice be called a debate—arose over the last 10 words. Remarks were made for some two hours by Dr. LORIMER HART, Mr. R. B. ANDERSON, Dr. J. HADDON, Dr. BERNARD O'CONNOR, Dr. BRASSEY BRIERLEY, and others, in the course of which it was seriously proposed that the discussion on the report should be commenced *de novo* paragraph by paragraph. Finally, Mr. G. BROWN proposed that the sentence should simply run, "but the resolution was lost," which was carried.

Mr. VICTOR HORSLEY then said that he wished to draw attention to a leading article which had appeared in the *British Medical Journal* previously to the Exeter Hall extraordinary meeting. He contended that this article was not only an instance of *suppressio veri* but also of *suggestio falsi*. The article had intimated that discussion of the new articles which were desired to codify certain conditions would be allowed. At the meeting no discussion took place, while the new articles did not codify the machinery of the Association in the sense of amalgamating and simplifying its working, but changed the constitution of the Association. Mr. Horsley also complained that the report of the meeting presented to the members in the *British Medical Journal* was very incomplete. He therefore moved as an amendment that the following paragraph be omitted from that section of the report which spoke of the *Journal*:—

> The Council has every reason to believe that the *Journal* has proved increasingly useful to members. The publication of the proceedings of the last annual meeting and of its sections was commenced immediately after the conclusion of the meeting, and was completed before the end of November.

Dr. DAWSON WILLIAMS, who rose for the first time to address an annual meeting of the Association, regretted that his remarks were not to be on a more pleasant topic, and said that he took the entire responsibility for what appeared in the *Journal* and did not desire to shield himself behind the Council. He wished to be quite frank and would say that when the particular leading article to which Mr. Horsley had referred was written he himself had no idea that discussion would not be allowed. With regard to the observation in the same leading article to the effect that the design of the new articles was to codify, amalgamate, and make simple the articles a charge of *suggestio falsi* was made, Dr. Dawson Williams did not allow that that was an inaccurate statement of what the intentions of the new articles were. The intention was that the by-laws should be amalgamated with the articles; the intention was that the articles and by-laws should be codified; for if the articles were looked at it would be found that there were special resolutions amending articles, and the intention was to make certain additions. He was, however, inclined to admit that in the article referred to it was not sufficiently clearly stated what it was these additions were. As to the report of the meeting he could only print what was supplied to him. He considered it necessary that the report should appear in the *Journal* for the week in which the meeting took place and owing to the *Journal* going to press upon the day following the meeting a *verbatim* report was not practicable.

Mr. VICTOR HORSLEY eventually consented to withdraw his amendment on condition that his speech and the reply of Dr. Dawson Williams should be printed *verbatim* in the *British Medical Journal*. The report was then agreed to as amended, and the meeting adjourned.

THE (ADJOURNED) FIRST GENERAL MEETING.

The adjourned meeting was held on Tuesday evening in the Lyceum Theatre at 8.30 for the delivery of Dr. Elliston's presidential address. The attendance was good and amongst those present were the Mayor of Ipswich, Sir Charles Dalrymple, M.P., Mr. Alderman C. H. Cowell and Mr. Alderman S. R. Anness, together with several of the town councillors.

The MAYOR (Mr. W. A. Churchman) made a feeling reference to the deaths of the King of Italy and of the Duke of Edinburgh and moved:—

> That the President and members of the British Medical Association, assembled at their annual meeting, together with the townspeople of Ipswich, desire respectfully to express to Her Most Gracious Majesty their deep sorrow and sympathy at the severe loss Her Majesty has sustained in the sudden decease of the Duke of Edinburgh, and trusts the Almighty may afford to Her Majesty and the members of the Royal Family abundant consolation.

The resolution was unanimously agreed to.

The MAYOR then, in a few felicitous phrases, welcomed the members of the Association to Ipswich, and congratulated Dr. Elliston and the townspeople upon his selection as President, which they all looked upon as a very great honour.

Dr. ELLISTON rose amidst applause and thanked the Mayor for his kindly words. He then proceeded to read his presidential address as follows:

THE PRESIDENT'S ADDRESS.

[Dr. Elliston took as the title of the address "Some Incidents in the Evolution of the Modern Physician," and commenced by welcoming most heartily to East Anglia the sixty-eighth annual meeting of the British Medical Association. After commenting upon the growth of the Association during the quarter of a century since its last meeting in East Anglia and after detailing the various literary and scientific reasons why Ipswich should prove an interesting place of reunion, he continued:—]

East Anglia and Medicine.

It is 26 years ago since this great association met in East Anglia, in the city of Norwich, and it speaks for its ever-growing importance and utility that on that occasion there were some 6000 members only, and the scientific business of the meeting was conducted in four sections. On this occasion, the first meeting of the nineteen hundreds, the members have increased to over 18,000, of whom 4000 are members of our Colonial branches, and the scientific work needs 13 sections. The town in which we are assembled is one of much commercial importance. Manufacturers and merchants do a considerable business with many of our colonies. It is an ancient town, and there are many beautiful specimens of old houses, gateways, and corner posts. To those who desire a better acquaintance with its history I would refer them to "Round About Ipswich," by the late Dr. J. E. Taylor;

Corner Posts," by Mr. J. S. Corder, recently published. Great Englishmen have been associated with Ipswich in the past—Nicholas Bacon, the Lord Keeper, was a freeman of Ipswich; his son, the great Lord Bacon, represented Ipswich in two Parliaments, and in more recent times Lord Nelson was high steward. Thomas Gainsborough lived and painted here. Charles Dickens found Ipswich to be worthy of many scenes for his fertile pen; but the personal association which throws lustre upon Ipswich is the fact that the great Cardinal Wolsey was born here. It is still, I think, a standing reproach to Ipswich that there is no monument to his memory, except one that he built himself, and which is the sole remains of the great college he intended to have raised at Ipswich. Among the illustrious medical names associated with East Anglia are William Gilbert, Sir Thomas Browne, Edward Rigby, J. G. Crosse, Sir Astley Cooper, the Brothers Paget Sir Thomas Watson (educated at Bury St. Edmunds), Jeaffreson (ovariotomist), Sir William Gull, John Hilton, Sir George Humphry, and many others, while among those yet living are some of the foremost names in the science of medicine.

The Development of British Medicine.

The early history of medical science in this country is concurrent with the advance of all scientific knowledge. During the Dark Ages men of learning had spent their time in translating and repeating what the Greeks had taught, until at last they had come to believe that Ptolemy, Galen, and Aristotle had settled most of the scientific questions and that no one had any right to doubt their decisions. In the annals of British science there was one exception to the apathy of Englishmen—Roger Bacon, the Franciscan friar, who is stated to have been the first man in Europe to make gunpowder. Green speaks of him as living before his time, but the probability is that travelling and studying natural science, and particularly alchemy in Italy, he imbued ideas of scientific progress that were absolutely dormant in this country until 250 years later. The continuous progress of British science commenced with the return of Thomas Linacre to Oxford from the Italian universities, whence he came imbued with what was termed the "new learning," then recently introduced by the Greek professors who had been attracted to Italy. At this time the learned of all countries were profoundly impressed by the recent discovery of America, by the scientific discoveries of such men as Copernicus and Paracelsus. The printing press was changing the conditions of life, and literature became the common property of all. The great event in the sixteenth century, so far as medicine is concerned, was the success of Thomas Linacre in persuading the King to grant a charter to a small body of medical graduates, who were thenceforth called the Royal College of Physicians. He succeeded, it is said, principally through the great and powerful help of Cardinal Wolsey. The charter of the Royal College of Physicians was granted on Sept. 23rd, 1518. It gave them the sole power to license to practise physic in London or within seven miles radius, with other privileges which were confirmed by a statute of Henry VIII. and extended to the whole of England. Linacre was the first President, and he held office to the end of his life.

In 1540 the Barbers and Surgeons were united by Act of Parliament, 38 Henry VIII., cap. 42. They were incorporated as the "Masters or Governors of the Mysterie and Commonalitie of Barbers and Surgeons of London." Thomas Vicary, Serjeant Surgeon to Henry VIII., who had been previously Master of the Barbers' Company, was the first Master of the combined Companies. The Company employed Holbein to paint a picture with the King on his throne, who, with his two physicians, Sir William Butts and Dr. John Chantre, with his apothecary kneeling on his right, presents the Act, which is painted with a seal as if it were a charter, to Vicary, who, with 14 other barbers and surgeons, is on his knees. In 1543 the irregular practitioners of London were protected by Act, and became one of the corporations of the City, and both by royal charters and by Acts of Parliament exercised the power of granting licences to practise medicine. In 1505 the Royal College of Surgeons of Edinburgh was founded, and in 1599 the Faculty of Physicians and Surgeons of Glasgow.

Scientific Medicine.

Soon after the birth of the new learning the work of Vesalius, the brilliant young Belgian, aided by his contemporaries Fallopius and Eustachius, raised anatomy to a science based upon the dissection of the human body itself, in addition to that of animals.

It was at the very commencement of the seventeenth century that the original research of two great English physicians, Gilbert and Harvey, completely altered the position of our country in scientific advance. Hitherto there had been no contribution of importance; from this time, however, a complete change came over the scene, and from that day to this our countrymen have taken a conspicuous part in the solution of the many scientific problems and discoveries of the last three centuries. Our East Anglian county of Essex has the honour to be the birthplace of one of these illustrious physicians and the resting-place of both. William Gilbert was born and buried at Colchester, and at Holy Trinity Church there is a monument to his memory. He died unmarried, at the early age of 57 years, in 1603. William Harvey died in 1657 and was buried at Hempstead, in the same county, in his eightieth year.

William Gilbert—or Gilberd as it is spelt upon his mural tablet—was born in the same year that Vesalius was appointed professor of anatomy at Padua, in 1546. He was educated at Cambridge and became a Fellow of St. John's in 1561. In 1573 he settled in London and became subsequently physician to Queen Elizabeth and President of the Royal College of Physicians. His leisure hours were given to chemistry and magnetism. In 1600 he published his "De Magnete." He established the magnetic nature of the earth and he conjectured that terrestrial magnetism and electricity were two allied emanations of a single force. He was the first to use the terms "electric force" and "electric attraction" and to point out that amber is not the only substance which when rubbed attracts light objects, and he described how to measure the excited electricity by means of an iron needle moving freely on a point. He described the properties of the magnet and its attraction and its direction in the relation of the poles of the earth.

William Harvey, the discoverer of the circulation of the blood, was born at Folkestone, graduated at Cambridge, subsequently travelling through Germany and France, and enrolled himself as a student of the University of Padua. His name heads the list of what was called the Jurist University for the years from 1600 to 1602. Here he studied under the celebrated surgeon and anatomist Fabricius. Upon his return to London he joined the College of Physicians and was shortly after his commencement of practice appointed physician to St. Bartholomew's Hospital. In 1615 he was appointed Lumleian Lecturer, an appointment which he held with more or less interruption due to the political disturbances of the times until 1656. He was physician to James I. and Charles I. There are many evidences that his eminence was appreciated by his contemporaries. In 1620, for instance, he attended a conference with representatives of the College of Physicians to protest against the proceedings of the Surgeons, who were moving in Parliament in their own interests, but he failed to induce his own university to coöperate with the College of Physicians. During the Civil War he was in attendance upon the King, and while quartered with him at Oxford he was elected Master of Merton. The work of William Harvey which has immortalised his name in the annals of medicine was published in the year 1621 at Frankfort as "An Anatomical Treatise on the Movement of the Heart and Blood in Animals." Mr. D'Arcy Power, in his admirable contribution to the "Masters of Medicine," says, "Harvey chose Frankfort as the place for the publication of his book because the annual book fair held in the town enabled a knowledge of his work to be more rapidly spread than if it had been issued in England." His researches upon this subject had long occupied his attention, and had been referred to from time to time in his Lumleian Lectures from the year 1606 onwards. The bent of his mind and his method of departure are explained in his book, when he says, "I profess both to learn and to teach anatomy not from books, but from dissections; not from the position of philosopher, but from the fabric of Nature." The results of Harvey's observations are the more remarkable when we consider the scanty instruments and appliances then available, contrasted with our own time when the senses, the arts, and the sciences are all brought into requisition for the discovery and analysis of objective symptoms. The microscope was as yet undiscovered. The number of pulse-beats was not measured by a watch until nearly a century after Harvey's time. In his day, according to Dr.

Norman Moore, physicians contented themselves with estimating the character of the pulse rather than its precise rate. Specialism as now understood did not exist, and Harvey was a surgeon as well as a physician. He performed surgical operations to which he frequently refers. The brilliant work of Galileo, Gilbert, and Harvey, the awakening philosophy of Francis Bacon in this country and Descartes in France, gave an impetus to original research and the investigation of causes that was remarkable in upsetting ancient traditions, and little by little real observation and experiment took the place of mere authority.

The Royal Society.

It was about this time that a small body of students assembled at Oxford in 1645 who were later, in 1662, to be known as the Royal Society. It was established as an association of men interested in the development of mathematical and physical science. It is the oldest scientific society in Great Britain, and one of the oldest in Europe. Italy had already established two societies in the time of Galileo and Torricelli. In Germany the Imperial Academy of the Curious in Nature was founded in 1662. The famous French Academy of Science was legally established by the French Government in 1666. All these societies greatly influenced scientific research, and many men who were hitherto unable to publish now read papers at their meetings. Of our own Royal Society it is recorded in the first journal book of the society that these persons met together on Nov. 28th, 1660, to hear Mr. Wren (afterwards Sir Christopher Wren) lecture at Gresham College, London, mentioning twelve names, including three physicians, and that after the lecture they returned to converse and pass resolutions for future guidance. At one of their early meetings 52 was fixed as the number of the society, persons of the rank of Baron, Fellows of the Royal College of Physicians, public professors of mathematics, physics, and natural philosophy of both Universities being supernumeraries. In October, 1660, the King offered to be entered one of the society, and next year the society was incorporated under the name of "Royal Society," the charter of incorporation passing the Great Seal on July 15th, 1662. Soon after incorporation the Royal Society published papers by Malpighi, who by the microscope revealed the minute infinite particles of living bodies.

Somewhat earlier than this two of our countrymen—Boyle, son of Lord Cork, and John Mayow—did much for progressive research and anticipated some of the great discoveries in chemistry and physiology of a century later. Boyle proved that a candle could not burn or an animal breathe without what was afterwards proved to be oxygen gas. These observations were said to have been attentively listened to at the early Oxford meetings of Wilkins and his friends by a young physician, John Mayow, who died at the early age of 34 years, but not before he had proved that air was made up of two portions, the one heavy which supports flame and light, which he called "fire air," and which was subsequently discovered to be oxygen; the other light, useless for living and breathing, and this was the larger portion, which we now call "nitrogen."

Practical Medicine.

Practical medicine in Great Britain was developing in this century; a pharmacopœia had been issued, cinchona bark was introduced; and botanical gardens were established. The teachings of Francis, Lord Bacon, and subsequently of John Locke, influenced the direction of thought, while the learning and superb common sense of that great physician Sydenham gave effect to the general advance of this period.

In surgery the growth was slow, principally through the general want of knowledge of anatomy acquired by dissection; but two Englishmen had distinguished themselves in this branch—Nathaniel Highmore and Thomas Wharton—the former discovering the cavity in the superior maxillary bone which is still known by his name and Thomas Wharton discovering the duct of the maxillary gland which is still recognised as Wharton's duct. The diary of Mr. Samuel Pepys illustrates the primitive method of procedure at that time. He says that "on February 27th, 1663, he walked with Commissioner Pett to Chirurgeons' Hall, we being all invited thither and promised to dine there, where we were led into the theatre, and by-and-bye came the reader, Dr. Tearne, with the Master and Company, in a very handsome manner, and, all being settled, he commenced his lecture, and his discourse being ended, we had a fine dinner and good learned company, many doctors of physic, and we used with extraordinary great respect." He also speaks of the gilt cup the gift of Henry VIII., with bells hanging to it, which every man had to ring by shaking after he had drunk up the whole sup. There is also, he says, a very excellent piece of the King, by Holbein, that stands up in the hall, with the officer of the Court kneeling to him to receive the charter.

The man who of all others at the early part of the eighteenth century gave an impetus to medical education was the illustrious Boerhaave, who at the University of Leyden attracted students from all parts, and particularly from this country. He was elected lecturer in 1701 and a few years later occupied the chair of chemistry. He shares with Dr. Hales, the great English chemist, the honour of founding the science of organic chemistry. So highly was Boerhaave esteemed by his fellow-countrymen that upon his recovery from a serious illness in 1722 there was a general illumination of the town of Leyden.

At this time there was practically no systematic medical training in the British Isles, but there were isolated attempts at special instruction. A refugee surgeon, Brussière, settled in England in the time of Queen Anne, and for the first time gave lectures in anatomy in England. In 1711 Dr. Richard Mead lectured and continued his lectures for four years to the Barber Surgeons. In the same year Cheselden commenced a series of lectures which continued for 20 years. The first Munro opened a similar course at Edinburgh. John Rutherford settled in the same city in 1721. Speaking of him, his grandson, Sir Walter Scott, says: "He was one of those pupils of Boerhaave to whom the school of medicine in our northern metropolis owes its rise." Together with Sinclair, Purvis, and Innes he established a laboratory and taught the rudiments of chemistry and other branches of physics. In 1766 Rutherford was appointed Lecturer in Medicine and until 1785 he delivered the lectures in Latin. He founded clinical teaching in Edinburgh. The success was so great that the managers of the Royal Infirmary appointed a special ward for the exclusive use of Rutherford. This laid the foundation of that form of teaching in which Edinburgh has held proud pre-eminence.

Increased Study of Anatomy.

Speaking of the history of medicine in the eighteenth century Lecky says: "A still more important fact in the history of medicine was the increased study of anatomy. The popular prejudice against dissection which had for centuries paralysed and almost prevented this study still ran so high in England that in spite of the number of capital punishments it was only with great difficulty the civil power could accommodate surgeons with proper subjects, and all publicity was studiously avoided. With such a state of feeling it is not surprising that the English medical school in the beginning of the eighteenth century should have been far inferior to that which gathered round the chair of Boerhaave at Leyden." In London there was no concrete medical school until quite late in the century. William Hunter came to London and commenced to lecture in 1747; he became a member of the Corporation of Surgeons, and was appointed Obstetric Physician to the Middlesex Hospital in 1742. He is stated to have been an early riser and a man of untiring energies. He was undoubtedly the first great teacher of anatomy in London, and we owe his selection and advance to Dr. James Douglas, an anatomist and obstetrician whose name is associated to this day with modern anatomists as the discoverer of Douglas's pouch.

The advancement of medicine and the allied sciences in the eighteenth century commenced with the contributions of Boerhaave and Hales in organic chemistry, while Buffon taught natural history, and the Swede Linnæus patiently worked out the minute characters of animals and plants. In physics the Scotch physician Black proved the amount of heat dormant in water and steam, which Watt afterwards applied to the steam engine. Electricity was greatly advanced by Benjamin Franklin, the American, who attracted lightning from the sky and worked with it in his own laboratory. Galvani found the wonderful power hidden in the nerves of the frog, and Volta showed how powerful electricity could be produced by two metals placed in acid and water, and this could be carried along a wire of any length which touched the battery at both ends. In physiology great advances were made by Haller, Bonnet, and Spallanzani. John Hunter, by his untiring energy, industry, and perseverance founded the science of comparative anatomy, and as an anatomist and as a practical surgeon built himself an everlasting fame.

Birth of Chemistry.

The most remarkable scientific advance was undoubtedly

in the science of chemistry. Almost to the last quarter of the century the theory of "phlogiston" had confused and mystified the researches of the many great and distinguished scientists who had worked in this direction. The important part played by our countrymen in the elucidation of truth is highly satisfactory. The discovery of the gases which enter into the combination of air, water, and fire transferred the alchemy of old into the modern science of chemistry. It was the discoveries of Black, Priestley, and Cavendish, and the independent work on similar lines of the great Swedish chemist, Schiel—himself a practising apothecary—that enabled Lavoisier to recognise the value of the discoveries and proclaim their effects upon science in his "Elements of Chemistry." At the early age of 51 years this philosophical chemist was guillotined by his countrymen in 1794, during the French Revolution. Black discovered carbonic acid in 1756, Cavendish hydrogen in 1766, Rutherford nitrogen in 1772; and it was not until 1774 that Priestley—a Nonconformist minister at Leeds—discovered oxygen. It was also independently discovered by Schiel in 1775. They both deserve credit. Priestley's discovery was made with red oxide of mercury; he heated it, and found that a gas came off, which he collected, and he experimented with two mice and he found that they breathed it and lived much longer than in ordinary air; then he breathed it himself and found that he felt singularly light and easy for some time after. "Who can tell," he writes, "whether this pure air may not become a fashionable luxury. As yet, only two mice and myself have had the privilege of breathing it." It is only of recent years that the great value of the inhalation of oxygen gas has been recognised and utilised in the treatment of certain diseases of the heart and lungs. I think many of us could bear testimony to its life-saving properties in cases which appeared hopeless.

[After referring to the practical work done in the eighteenth and early nineteenth centuries by Jenner, by Dr. Richard Mead (who discovered the acarus scabiei), by Dr. J. Lind (who traced scurvy to dietetic errors), by the elder Heberden, by Dr. Robert James (the inventor of James's Powder), by Dr. Matthew Baillie, by the brothers Hunter, by Lettsom, Abernethy, Charles Bell, Cheselden, Astley Cooper, Pott, Hey, and many others, Dr. Elliston continued:—]

Medical Legislation.

The important legislation of the nineteenth century was the Apothecaries Act of 1815. This Act has been proved to be one of the greatest boons ever conferred upon the medical profession, and whatever may be the sentimental objection to a learned profession being connected with traders we are bound to remember that to those who sought the Act of 1815 we are indebted for a reform which has been far-reaching in its results. Previously to this Act the education of the medical practitioners of England and Wales was entirely optional on their part, and although many of them possessed degrees or licences of the Universities or Colleges the greater number possessed no such qualification and many of them were wholly illiterate or uneducated. About the year 1850 a preliminary examination in arts was instituted as a necessary and independent requirement before proceeding to the medical curriculum. In 1858 the Medical Act became law, and by this Act the L.S.A. of London was permitted to practise throughout Scotland or Ireland. The Apothecaries Amended Act passed into law in 1872. Women were admitted to practise in 1876. In 1878 the pharmaceutical chemists were licensed by Act. It is worthy of observation that the State has hitherto not interfered to prescribe the subject matter or the minimum standard of medical examination, although there has been at least one attempt by the Government of the day to establish a uniform minimum. Under the beneficent legislation of the century, and particularly by the establishment of the General Medical Council, jealousies between the different branches of the profession have mainly disappeared, and it is difficult now to realise that at the commencement of the present century it was far otherwise, thus, we find a young physician advanced by his College in 1808 as a reward for a pamphlet against the growing pretensions of army surgeons. The use of wise legislative enactments in the social influence and status of the profession soon became apparent, but of course its full effects were not evident until many years had elapsed. It is quite within my memory that the only qualification recorded in many instances in the annual "Medical Directory" was "in practice prior to 1815." It is not a little singular that the Apothecaries Act has gradually extinguished the apothecary as then understood. I can remember an apothecary's shop in this town. That has now become a thing of the past, as will be soon, I trust, what is called the open surgery of to-day. With the better education required and the institution of examinations a different class of students were attracted to medicine, and they were rarely satisfied with the apothecary's licence but sought further a surgeon's diploma.

The Medical Press.

The growth of the medical press and the influence it had upon the medical profession commenced with the efforts of William Sharman, M.D., who was born at Harwich in 1767. He commenced in 1810 to edit a periodical which was styled the *New Medical Physical Journal or Annals of Medicine, Natural History, and Chemistry*. It was in existence in 1815.

In 1815 Thomas Wakley was a student of the Borough Hospitals; the greater part of his medical education was acquired at the Grainger School. In 1817 he became a M.R.C.S. and commenced practice. Fortunately, perhaps, he did not altogether succeed and his great talents were turned in the direction of journalism. He founded THE LANCET in 1823 with the primary object of disseminating much needed information hitherto regarded as the exclusive property of members of the London hospitals and also with a view of exposing the family intrigues that influenced the appointments in the London hospitals and the medical corporations. For the first ten years of its existence THE LANCET provoked a succession of fierce encounters between the editor and the members of the privileged class in medicine. In the first number Wakley made a daring departure in commencing a series of shorthand reports of hospital lectures. On Dec. 10th, 1824, Mr. Abernethy applied to the Court of Chancery for an injunction to restrain THE LANCET from publishing his lectures. The injunction was refused by Lord Eldon, on the ground that official lectures in a public place for the public good had no copyright vested in them. Mr. Wakley then commenced a regular issue of hospital reports of cases and notable operations. The irritation at them was so great that his exclusion from St. Thomas's Hospital was ordered. He also carried on a campaign against the Royal College of Surgeons of England. Mr. Wakley and his successors have done work which has advanced the general interest of the profession by leaps and bounds, and during the long period of its usefulness THE LANCET has always availed itself of the best talent, and many of those who have achieved success in other departments have given their early work to the advancement of medical journalism. At the present time the influence of the press is enormous. Our own *Journal*, reflecting the opinions of this Association, shares with THE LANCET and many other medical periodicals in guiding the profession upon every question to the direct issues constantly occurring.

[Dr. Elliston here acknowledged the impossibility of giving anything more than quite a brief enumeration of the brilliant work of the British physicians and surgeons of the nineteenth century. He alluded especially to the work of Richard Bright, of Hodgkin, of Thomas Addison, and of Sir William Gull (all of whom were members of the staff of Guy's Hospital), of Sir William Jenner, of Graves, of Hughes Bennett, Marshall Hall, Elliotson, Stokes, Alison, Sir Thomas Watson, the Farrs, Sir J. Simpson, Tyler Smith, the Budds, Spencer Wells, Bucknill, Tuke, Bowman, Hilton, Sir B. Brodie, Aston Key, Sir W. Lawrance, Robert Liston, Syme, Sir W. Fergusson, Sir George Humphry, and many others living and dead.]

It is not, perhaps, Dr. Elliston continued, so generally known as it deserves to be that William Jeaffreson of Framlingham in the county of Suffolk, an East Anglian surgeon, was the first surgeon in England to perform the modern operation of ovariotomy by a small centre incision. The circumstance, as recorded in the Transactions of the Provincial Medical Association of 1837, are as follows: "Mr. Jeaffreson in 1833 lost a patient suffering from an abdominal tumour. She died from tuberculous disease of the lungs and, obtaining the consent of the friends, he made a post-mortem examination, which satisfied him that the tumour could have been removed, and but for the disease of her lungs her life might have been spared." In November of the same year Jeaffreson and his friend King attended together a lady in her confinement with a small tumour. They subsequently advised an operation and

in May, 1836, a central incision was made, about one and a half inches long, the cyst tapped, withdrawn, the pedicle secured by ligature, and the ends cut off short. The wound was adjusted by two sutures and napkins wrung out in the coldest water were constantly applied to the wound. Sulphate of magnesia was administered every four hours and all went well until the tenth day, when Jeaffreson was called to his patient at 3 A.M., to find her pulseless, with incessant vomiting and hiccough and griping pains in her body. A stimulating enema with two grains of opium gave her speedy relief and she recovered. His friend and neighbour King, at Saxmundham, Suffolk, about 10 miles away, operated a few weeks later with complete success, his incision being somewhat longer—about three inches. Two years subsequently a third East Anglian surgeon, Crisp of Harleston, who lived about 20 miles from Jeaffreson, was also successful with an incision of two inches in length. These three cases, which were performed by three surgeons in general practice in this county were the first in England in response to the doctrines of William and John Hunter and are the more remarkable when we consider that no operation of the kind was attempted in London until four years later and no ovariotomy was performed in a London hospital until 10 years after Jeaffreson's case.

Antiseptics and Anæsthetics.

The two great discoveries of the nineteenth century in connexion with both medicine and surgery are the antiseptic treatment (for which we are indebted to the genius of a living surgeon, Lord Lister) and the use of anæsthetics. The anæsthetics now in general use are nitrous oxide gas, discovered by Sir Humphry Davy in 1800; sulphuric ether, by Faraday; and chloroform, by Liebig. I shall not detain you by a history of the introduction of anæsthetics into surgical practice, but as we have still living in East Anglia a most distinguished surgeon (Mr. William Cadge), who was present on the occasion of the first operation in London under the influence of ether I thought it would be interesting to hear his record of the circumstances. Mr. Cadge says: "Robert Liston was the first surgeon in this country to use ether, and those who were present at University College Hospital on Dec. 21st, 1846, and witnessed the complete and perfect success of that first venture, will not easily forget the dramatic character of that scene. I was present and assisted at the operation—amputation of the thigh by the double flap method. Someone present timed the operation; it took 30 seconds; the few arteries were tied and all signs of blood cleared away. A towel was then thrown over the stump and we watched anxiously for the patient to show that he was not dead; he presently woke up, and when asked once or twice if he could stand the pain of the operation, he accused us of cruelly trifling with his feelings, and when the towel was removed and he saw the naked stump he burst into tears, and I thought Liston would do the same."

[Dr. Elliston concluded an interesting address by a *résumé* of the various Acts of Parliament recently passed having for their object the maintenance and improvement of public health.]

At the conclusion of the address, which was listened to with close attention,

Mr. HOWARD MARSH proposed a vote of thanks to the President for his address, which was marked by great research, clear statements, and a due appreciation of the great truths passed in review.

Dr. I. H. CAMERON (Toronto) seconded the motion and expressed the pleasure with which they had all listened to a survey of 500 years of the history of medical and surgical art.

The motion was passed *nem. con.*, and the PRESIDENT briefly replied.

Mr. WARD COUSINS, on behalf of the Council, offered a hearty welcome to the foreign and colonial representatives, to which Professor RODDICK of Montreal and Professor NICOLAYSEN of Christiania replied.

The meeting then terminated.

SECOND GENERAL MEETING.

The second general meeting was held in the Central Hall of the Higher Grade School on Wednesday afternoon, the room being well filled.

The President of the Council, Dr. ROBERTS THOMSON, declared the names of those not returned to the Council and also the names of the newly-elected members. He also announced that an invitation had been received from the Gloucester branch asking the Council to hold the meeting of the Association in 1891 at Cheltenham and that the Council recommended that the invitation be accepted. This was agreed to and Dr. G. B. FERGUSON was appointed President elect.

The PRESIDENT then called upon Dr. Pye-Smith to deliver the address in medicine which will be found at p. 309.

At the conclusion of the address Dr. SAUNDBY moved, and Colonel KENNETH MACLEOD, I.M.S., seconded, a vote of thanks to Dr. Pye-Smith. This was carried unanimously, and Dr. PYE-SMITH returned thanks.

The PRESIDENT then said that it was his very pleasant duty to award the Middlemore Prize for 1900 to Dr. Ernest Maddox of Bournemouth. This prize is of the value of £50, and was awarded this year for researches in ophthalmology.

The report of the Parliamentary Bills Committee was then taken, and Mr. R. B. ANDERSON made a personal explanation with reference to some remarks which he had made in moving a rider to the sections of the report dealing with the Midwives Bill upon the previous day, the accuracy of which had been called in question by Mr. Victor Horsley.

On the report of the Scientific Grants Committee, Professor BYERS urged that the distribution of the grants was too much centralised. The grants should, in his opinion, be spread more over the country. He also objected to the giving of grants to rich London hospitals.

Dr. HUDSON moved—

That the scientific grants be discontinued and the money devoted as prizes to work already done.

At present he considered that the money was frittered away.

As, however, no seconder came forward the motion dropped.

On the report of the General Practitioners and Ethical Committee Dr. C. F. K. MURRAY, president of the Cape Town Branch, spoke of the growing difficulty at the Cape of dealing with friendly societies and clubs on the matter of a wage-limit. The medical practitioners in South Africa looked to the Council for guidance in this matter and he suggested that those at home who had had experience of the difficulty of the question should help their brethren abroad in a practical manner by expressing their opinion, and to this end he submitted the following motion:—

That this meeting resolves that the Council be requested to issue a circular to all branches of this Association inviting them to express an opinion and to submit proposals on the question of the "wage limit" as applied to clubs, provident dispensaries, and societies, &c., with a view to suggesting a reasonable and fair working basis; furthermore that it be an instruction to the Council to report and advise this Association thereon at its next annual meeting.

The motion was seconded by Mr. G. H. BROADBENT, who thought it shocking to hear that such a state of things existed in South Africa. He considered that as the question had been before the Council for eight years it was quite time that something was done by them in the matter.

The motion was then agreed to, with one dissentient.

The PRESIDENT then called upon Mr. Victor Horsley to submit his motion, which stood in the following terms:—

That a committee be appointed to consider and report upon the best means of reorganising the constitution of the British Medical Association, such committee to furnish a provisional report to the branches by March 1st, 1901.

Mr. HORSLEY sketched his idea of what the reformed constitution of the Association should embrace. He referred specially to the creation of delegates from the branches to the Council and deprecated the view so commonly held that a delegate must be in a subservient position. He also referred to the establishment of a medico-political bureau and of an information bureau. He concluded by suggesting that the proposed committee should consist of 23 members, and if his resolution were accepted he would read the names which he proposed to submit to the meeting.

Dr. BRASSEY BRIERLEY in seconding the motion said that as Mr. Victor Horsley's motion covered most of the points with which he had dealt in his notices of motion he would withdraw them all except one, which he would bring forward later.

Mr. T. J. VERRALL, a member of the Council, then rose in support of the motion.

Dr. A. COX wished to move a rider dealing with the principle of delegation. It was, however, ruled by the PRESIDENT

that the rider was out of order. It could, however, be put as an amendment.

Dr. COX, however, withdrew it at the suggestion of the PRESIDENT, intimating his intention of bringing it up as a fresh motion if Mr. Horsley's proposal were accepted.

Mr. R. BRUMMITT asked Mr. Horsley if he would fix an earlier date than March 1st, as the Australasian branches would thereby have an opportunity of expressing their opinion on the subject.

Mr. HORSLEY agreeing to this the date was altered to Feb. 1st, and his motion was thereupon put and carried unanimously.

Mr. HORSLEY then read out the names he proposed for the committee, upon which a long discussion ensued, it being eventually agreed that the committee should consist of 24 persons, of whom one-half should be nominated by the Council and their names would be handed in to the general meeting which was to take place on the following day. The other 12 members were to be nominated by the general meeting, with whom also the final selection of the whole committee was to rest.

Dr. A. COX again brought forward his original rider to Mr. Horsley's resolution as a new motion, which, after some discussion, was lost, it being felt that the hands of the new committee appointed to consider the alterations in the constitution of the Association should not be tied in advance.

The meeting then adjourned.

THE SECTIONS.

MEDICINE.

WEDNESDAY, AUGUST 1ST.

The President, Dr. T. BUZZARD (London), stated that he had been requested not to give a formal introductory address.

Influenza as it Affects the Nervous System.

Dr. JUDSON S. BURY (Manchester) opened this discussion. He referred to the diversity of symptoms of influenza in different epidemics and in different persons which made it very difficult to construct a scheme of symptoms which could be said to represent a typical case of the disease. Four types of the disease could be recognised, distinguished by the organ chiefly affected; (1) affecting the mucous membranes; (2) the gastro-intestinal tract; (3) the heart; and (4) when the nervous system was exclusively attacked. In all these forms and in nearly every case the nervous system was profoundly affected, as evidenced by the pain in the head and the back, which was seldom absent, hyperæsthesia, delirium, and depression, all symptoms which were the result of the action of a toxin on the nervous system. In cases where the more ordinary nervous symptoms appeared to be absent careful observation would show others, such as undue dyspnœa in pneumonic cases and tachy- and brady-cardia in cardiac cases which were essentially nervous in nature. At the same time he was not prepared to say that in every case the influence of the toxin on the organ was exerted solely through the nerve. He recognised two chief groups of nervous affections following the disease—those developing during the febrile stage such as meningitis and encephalitis where the brain tissue was directly affected, and those arising later, due probably to a less virulent toxin, and in which while visible degeneration of nervous matter might be discovered in a proportion yet in many nothing of the kind could be seen. In the first group, again, he distinguished a comatose and a delirious type. The former was a very serious state, often ending fatally, and he quoted at length one or two cases. Post mortem a condition of hæmorrhagic meningo-encephalitis was found and a drawing of the condition in the pia-arachnoid was exhibited, showing endarteritis apparently of recent origin with thrombi in the diseased vessels. Pfeiffer's bacillus, though difficult to demonstrate, had been found, and cases of meningitis were also due to this as well as sometimes secondary to otitis media or nasal suppuration. Other results of influenza were cerebral embolism, thrombosis, and abscess. The delirious type was common in children. The spinal cord might be attacked together with the brain or independently. Generally it was affected after the initial attack but sometimes during it. The enumeration of every form of nervous disease that had been reported as following influenza would be merely the enumeration of every known form of nervous affection of brain, spinal cord, or peripheral nerves. The peculiarity of the influenza toxin as distinguished from that of diphtheria was that it affected nervous tissues haphazard and not so much in groups. He related a series of cases illustrative of his remarks, referring particularly to the various forms of multiple neuritis, and asked for the opinion of members as to whether in their experience the nerves affected were most frequently the sensory or motor, and also if anyone present had seen cases where the respiratory muscles were paralysed. In conclusion, he said that it was possible that multiple neuritis might be due to bacilli as yet unknown and not to Pfeiffer's or the Klebs-Læffler bacillus, these being merely predisposing agents.

Sir WILLIAM BROADBENT (London) distinguished between the results of influenza due to toxins and those due to the bacilli of the disease. He thought the poison generally attacked the weak spot. He related a case of acute dementia following influenza. He thought that in the neurasthenic, neuralgic, and similar cases they had the effect of the toxin, while Dr. Bury's acute comatose type was probably similar in character to those cerebral attacks in malignant malaria where the vessels were found choked with parasites and leucocytes. He had seen a most acute case of the kind during an epidemic of influenza on board a training ship. Five boys became comatose and two died. The chaplain who had visited the boys was seized with the disease. Coma came on very rapidly. There were muscular rigidity and inability to empty the bladder, the temperature was 103° to 104° F., and the patient, though rallying after large doses of quinine hypodermically administered, died in a week. Another patient had meningitis, some paraplegia, and very extensive herpes round the loins. Another had unilateral convulsions of great severity, accompanied by no paralysis. This patient made a complete recovery which was retarded somewhat by long-continued sleeplessness. In a case which he considered to be due to thrombosis of the vessels of the right cerebral hemisphere the patient had left hemiplegia of slow and gradual onset. It was 10 years ago and he had continued to show progressive improvement ever since, and was now nearly well. He had seen a case of universal multiple neuritis which eventually proved fatal by implication of the respiratory muscles.

Sir PETER EADE (Norwich) thought the fact worthy of notice that the section was still discussing influenza ten years after its reappearance as an epidemic, whereas as far as they knew previous epidemics had disappeared much more rapidly. He could not agree with Sir W. Gowers that the incidence of the influenza poison was chiefly on the motor nerves. He thought that the medulla oblongata bore the brunt of the attack of the disease, and that this accounted for the frequency of heart disturbance. He thought that all these nervous symptoms were not true sequelæ but continuations of conditions which had existed during the primary attack. He related some cases of sleepy condition with bradycardia.

Professor CLIFFORD ALLBUTT (Cambridge), who said that he had not intended to take part in the discussion, insisted on the importance of correct diagnosis. He thought they ought to be extremely careful before asserting that any particular condition was the result of influenza, and that in many reported cases it was merely a matter of remote inference that such was the case. As an assistance in diagnosis he considered suddenness of attack a very valuable sign and instanced the case of a man who was seized while riding on horseback. With regard to the parts of the body most frequently attacked he agreed with the opener of the discussion that the anterior part of the brain was most frequently the seat of influenzal lesions and described a case under his own care where there had been very slight paralytic symptoms which disappeared but the patient remained aphasic, not when speaking slowly and deliberately but whenever he tried to talk fast. If there were certain areas preferentially attacked by the disease they ought to be ascertained. He doubted if it attacked weak points. He recommended lumbar puncture in meningo-encephalitic cases and bacterial diagnosis. He confessed that he was a pessimist in regard to prognosis in most of the cases under discussion.

Dr. NEWTON PITT (London) said that many cases of meningitis occurred in the early days of the influenza epidemic, but he was not sure that they were all due to the influenza bacillus. In one or two cases when it followed distension of the nasal sinus and antrum, &c., the bacillus had been found. In another a bacillus thought to be the diplococcus of Fraenkel was discovered but he would not like to say now that it might not have been the diplococcus intracellularis meningitidis. He referred to cases of influenza

which were quickly followed by enteric fever, and while thinking that the diagnosis was probably in many cases correct considered that the cases of meningitis were not more likely to be due to Pfeiffer's bacillus than these cases of enteric fever were. As a point in diagnosis he thought that in multiple neuritis due to influenza facial paralysis was more common than in others. He considered the affections of the heart to be due to disease of the nerves and not of the myocardium. He also thought that in many cases the irregularity of the heart's action was secondary and due to dilatation of the stomach produced by the original disease.

Dr. J. MACCORMAC (Belfast) doubted whether diphtheria was a specific infectious disease.

Dr. FRANK M. POPE (Leicester) related a case of the comatose type of encephalopathy in a boy in a large industrial school, and thought that in some cases injury might determine the point of incidence of the disease. In anosmia, where the nervous mechanism of the special sense affected was very close to the nasal mucous membrane where the poison entered, recovery was not likely unless it began early. He found that most of the cases following influenza that he had seen were in connection with the earliest epidemic, and thought the reason was that the people whose nervous system were likely to be affected were attacked on the first occasion and the less liable only remained, among whom, of course, in subsequent epidemics not so many cases were likely to occur.

Dr. S. K. MULLICK (London) thought motor nerves were more usually affected than sensory.

Mr. S. E. SOLLY (Colorado) related a case of hemiplegia in a young woman with aphasia which was almost certainly of influenzal origin and which ended in recovery.

Dr. R. SAUNDBY (Birmingham) considered that diabetes after influenza was a similar condition to diabetes occurring after any other acute disease and he regarded influenza as a fairly typical infectious process. As to the way in which the diabetes was produced he thought some cases might be due to a chronic interstitial pancreatitis.

Mrs. GARRETT ANDERSON asked that diagnosis should be very carefully made. They were too ready to call everything influenza. Diagnosis, however, did not much help treatment in these cases. She inquired into the conditions which might intensify the poison of influenza, thought that such a series of cases as Sir William Broadbent had mentioned as having occurred on a training-ship showed that overcrowding intensified the poison, and had seen similar instances among crowded communities, such as schools and nurses' and servants' quarters. Prognosis must in most cases be based on the recovery rate.

Dr. W. EWART (London) spoke of the different aspects which such so-called system diseases as locomotor ataxia, Friedreich's disease, and spastic paraplegia presented when they were the effect of influenza as contrasted with their usual appearances. Instead of beginning gradually and increasing in severity the first influenzal forms began acutely and progressed, at all events for a time, towards recovery. He gave instances of several of such cases. He hoped that from that discussion they might learn something of how toxins affect the spinal cord and brain, and inquired whether in cases where nervous diseases come on some time after the initial disease there are not some bacteria still living and producing their toxin somewhere in the organism, nasal mucous membrane, or elsewhere, and suggested that an efficient cleaning was necessary here, as after diphtheria, lest the convalescent should be a disseminator of disease for some time after apparent recovery.

Sir J. W. MOORE called attention to the psychical state of influenza patients which makes them believe that they are the subjects of organic lesions and thought that many cases of post-influenzal nervous disorder were purely subjective. He agreed that most cardiac symptoms were of nervous origin and not myocardial.

Dr. ST. CLAIR THOMSON (London) agreed that anosmia was frequently curable. He doubted whether it was possible to apply stringent antiseptic proceedings to the nasal mucous membrane. It was naturally aseptic but he agreed that cleansing might be done.

Dr. W. CALWELL (Belfast) asked for statistics with regard to deaths during chloroform inhalation of persons who had recently had influenza.

The PRESIDENT considered the discussion suggestive and valuable. On the broad question he had no doubt that influenza was capable of producing and often produced the gravest changes in the nervous system. It might act in two ways. There was a class of disease which was revealed by influenza—i.e., the disease brought to light some flaw unsuspected previously. He quoted a case of tabes made worse by the disease. In the same way he believed that cases of melancholia and mania were due to the displaying of flaws in the mental apparatus. After all, this was only a small part of the question. They had to deal with the direct effects of a virulent poison on the nervous system. One point he thought had not been touched on which he considered an evidence of the toxæmic origin of the diseases mentioned. In early days he had written on syphilitic disease of the nervous system and had pointed out the bizarre arrangements of the symptoms of these diseases. They might see one leg paralysed together with the opposite arm, one eye and the opposite leg, and other such arrangements which they did not see in ordinary cases of disease from such causes as senile internal change or the like. Now this sign had been generally recognised as a sign of disease produced by toxins. Dr. Medin of Stockholm had reported an epidemic of anterior poliomyelitis where, together with the changes resulting from diseases in the anterior corneal cells, there were facial pain, hemiplegia, affections of the lateral columns, and other symptoms. Again, Dr. W. Pasteur had brought before the Clinical Society a similar epidemic and had asked if he was justified in regarding these cases as anterior poliomyelitis as other and remote structures were involved. Dr. Buzzard then quoted the case of a strong working man who, as the result of influenza, had double optic neuritis with complete optic atrophy, nystagmus, and paralysis of all four extremities, intentional tremor of one upper extremity, and loss of knee-jerks, showing that the toxin had affected widely separated motor and sensory neurons. Two similar cases were also given, in the latter of which a post-mortem examination had shown marked change in the vessels and ground substance in the floor of the fourth ventricle. He thought such anomalous conglomeration of symptoms pointed most strongly to the toxæmic nature of these affections. They could not cramp and confine the grave nervous diseases of influenza into ordinary terms. They must either largely increase their nervous terminology or else not use it in this respect. Systems of motor and sensory neurons must form the basis of their new nomenclature. The diseases of the nervous system due to toxins had largely increased in late years and they were not all due to influenza, there being a great many unlabeled toxins at work, but many had still the disease for their cause.

Dr. JUDSON BURY replied, and as an instance of the value of such a discussion he said that it was dogmatically stated in Leichtenstein's work on influenza, perhaps the best up to date, that the respiratory muscles were never affected in post-influenzal multiple neuritis, yet two such cases had been related in that room that day.

SURGERY.

WEDNESDAY, AUGUST 1ST.

The Presidential Address.

Mr. HOWARD MARSH, F.R.C.S., surgeon and lecturer on surgery at St. Bartholomew's Hospital, opened the work of the section with the following speech:—

It has been agreed that there shall be no formal addresses at the opening of the various sections. I think members will endorse this arrangement. It may be possible to make such addresses interesting and perhaps even instructive; but they are in no way a necessary part of your proceedings and they would encroach materially on the very limited time which is at your disposal for the proper business of the meeting—the reading and adequate discussion of clinical papers. A very few remarks, however, which have a direct reference to the work of the section may be really useful. On some previous occasions so many papers have been accepted for reading that many valuable contributions could only be hurried through in abstract and no discussion was possible. This was unsatisfactory to all concerned. On the present occasion the object has been to cut the garment according to the cloth; in other words, to adjust the number of papers to the time that is available, so that each may have a fair hearing and be fully discussed. I anticipate that all who are present will regard this as the proper method. Two set discussions have been arranged on subjects both of which I feel certain members will regard as well worthy of their attention. Subdiaphragmatic abscess is no doubt a somewhat

rare condition, yet it may occur in the practice of anyone. It is highly dangerous to life, and both in regard to diagnosis and treatment it presents difficulties of a very grave and embarrassing order. As the subject will be introduced by Mr. Godlee, and discussed by those whose names are a guarantee of their knowledge and sound judgment, I am sure that valuable information will be forthcoming. The subject of fractures belongs to a different order. It is so old and familiar that it may appear at first sight to be too hackneyed and barren to be worthy of your notice. On second thoughts, however, I believe that it will be felt that the opposite is really the case. Long a mere matter of routine, the treatment of fractures has lately felt the influence of modern advance in other departments of surgery. The Roentgen process secures an accuracy of diagnosis which formerly was often impossible. The aseptic method makes operative interference safe, so that when necessary it can be adopted without hesitation, and it has become obvious that to secure the best results treatment must be applied not only to the fractured bone itself, but to the neighbouring joint and the muscles and other structures of the limb. All these are points that present themselves, and I feel certain that Mr. Bennett's paper, on which I know he has expended considerable time and labour, and the ensuing discussion will be attended with practical results of very material value which will establish and disseminate methods of treatment which will largely promote the welfare of patients and the credit of this department of surgery. As to papers to be read I will merely venture upon one or two brief and, as I may term them, official remarks. The time allowed to each paper is 15 minutes, and to the discussion 10 minutes for each speaker. We must, as I have said before, cut our garment according to our cloth, and if one member of the section takes up more than his share of the cloth, those who follow him must go short, so that conciseness, which must not of course impair clearness of statement and completeness of argument, will be a blessing which we shall all thoroughly appreciate and greatly applaud, while as your humble servant I shall be spared the distress of curtailing remarks which, however weighty and to the point, are materially overstepping the allotted time.

Subdiaphragmatic Abscess.

A discussion followed on Subdiaphragmatic Abscess which was introduced by Mr. RICKMAN J. GODLEE (London), who pointed out that though the condition was rare yet it had lately been made the subject of a lengthy monograph by Prag. He mentioned that Maydl had classified the causes of subphrenic abscess under many heads, and he intended on the whole to follow the classification. In itself subdiaphragmatic abscess was not a disease but merely a by-product of some other disease. It was usual to speak of two varieties, an extra-peritoneal and an intra-peritoneal, but these two conditions presented very different symptoms and were associated with very different dangers. The best definition of a subdiaphragmatic abscess was "a collection of pus, with or without gas, between the diaphragm and the structures in contact with it." Mr. Godlee proceeded to give an elaborate and exact account of the anatomy of the under-surface of the diaphragm, detailing the relations of it with the contiguous viscera. He pointed out that the diaphragm should be regarded not as a single dome but as two domes, to a great extent separated by the projecting bodies of the vertebræ. It was also important to remember that a large portion of the under-surface of the diaphragm was not covered by peritoneum, but in immediate contact with the liver, stomach, spleen, pancreas, suprarenals, and kidneys. As to the symptoms of the disease there were none which could be described as pathognomonic. In the early stages there might be hiccough, a stitch in the side as in pleurisy, and friction. He considered that much benefit in diagnosis might be derived from the careful use of the stethoscope. The abscess might give rise to dulness at the lower part of the chest and might be accompanied by displacement of the heart. It might be diagnosed from pleurisy by the fact that the movements of the chest were not impaired, that the upper limit of the dulness was not so well defined as in a pleuritic effusion, and that the breath sounds might be heard below the upper level of dulness. Mr. Godlee mentioned that in emaciated persons it was frequently possible to see through the intact chest wall the lower border of the right lung ascending and descending during respiration. This sign, if present, would be quite against the presence of a pleurisy or pleuritic adhesions. If gas was present in the abscess (the so-called subdiaphragmatic pneumo-thorax) the bell sound might be readily elicited. The tympanitic note might reach upwards even as far as the second rib, and yet the respiratory movement of the chest was not interfered with. He proceeded to consider in turn the causes of the abscess. 1. *Stomach.*—If a gastric ulcer ruptured the pus might be localised, even though it had been poured out into the peritoneal cavity. In other cases the rupture might occur into the small sac. The symptoms in such a case would be very different from those met with in a case in which the perforation of the ulcer proceeded very slowly, so that the stomach had time to become adherent to adjacent viscera. These chronic abscesses burrowed greatly, and when accompanied by serous effusion into the pleura were likely to be mistaken for cases of empyema. 2. *Intestine.*—In these cases the abscess resulted from the rupture of a duodenal ulcer or an ulcer of the transverse colon. Pus and gas collected, pushing the diaphragm upwards, sometimes to a very great degree. There might be no dulness when the patient was lying down, but a tympanitic note; yet if the patient stood erect some dulness was evident at the lower part. In operating on these cases mere drainage might be sufficient, but sometimes it might be possible to close the opening in the bowel. 3. *Cæcum and appendix.*—When a subdiaphragmatic abscess followed on disease of the cæcum or appendix the original inguinal swelling might become less obvious. The abscess was usually on the right side, but it might occur on the left. The pleura might be perforated and an empyema might form. 4. *Hydatid.*—Suppuration of a hydatid cyst of the liver or spleen might simulate an empyema. 5. *Liver and bile passages.*—Many abscesses of the liver were really perihepatic and might perforate the diaphragm. 6. *Kidney.*—A perinephral abscess might be a true subphrenic abscess, and occasionally a greatly enlarged pyonephrosis might extend so far upwards as to simulate a subdiaphragmatic abscess. 7. *Subcutaneous injuries.*—The abscess sometimes followed a blow without a wound of the skin; in this case the blow had probably caused the rupture of a previously existing ulcer, just as the removal of a breast had been followed by perforation of a gastric ulcer. 8. *Wounds* might give rise to the abscess by the introduction of septic material. 9. *Metastases.*—Mr. Godlee thought it was a little difficult to be sure what Maydl meant by this class. 10. *Ribs.*—Caries or necrosis of the ribs might cause this form of abscess. In these cases the suppuration was really in the substance of the muscle, and might give rise to numerous sinuses. 11. Collections of pus in the thorax might make their way downwards, so that caries of the dorsal spine and inflammation of the mediastinum might cause a subphrenic abscess. 12. Under the last heading Maydl put "Various causes.' One of these was actinomycosis; it progressed very slowly, and it hardly gave rise to true pus. It was probably a much more common cause than was usually imagined. Surgical treatment was unsatisfactory. Tuberculosis, peritonitis, and disease of the pancreas were also rare causes.

Mr. BRUCE CLARKE (London) said it was difficult to lay down general rules for diagnosis. In some cases the diagnosis could only be made by recognising that the patient was suffering from some obscure illness and by excluding other conditions. He was inclined to believe that an ulcer of the stomach or intestine was by far the commonest cause. In the treatment of these cases much help was obtained by inserting one hand through a laparotomy wound; thus the exact relations of the abscess could be made out and the best position for an incision could be found. A case illustrating this point was related. He objected to "metastasis" being given as a cause; the expression "a septic condition" was much better.

Mr. L. A. BIDWELL (London) had had six cases. In four of these a diagnosis of empyema was made, and of these four cases three were caused by an ulcer of the stomach and the fourth by an ulcer of the colon. He considered that the pus in a subdiaphragmatic abscess had a peculiarly offensive odour by which it could be distinguished from an empyema.

MRS. STANLEY BOYD (London) read the notes of a case of subphrenic abscess which had commenced with vague gastric symptoms and for some weeks an exact diagnosis was not possible. Ultimately a correct diagnosis was made and the abscess was opened and drained and, so far as the abscess was concerned, the patient improved, but died a little later from ulcerative endocarditis.

Mr. FULLER (Cape Town) urged the importance of a

bacteriological examination of the pus removed from the abscess by an exploring syringe, for if the bacterium coli were found it would be greatly in favour of a subphrenic abscess and opposed to an empyema.

Professor CAMERON (Canada) related a case in which a subdiaphragmatic abscess burst into the general peritoneal cavity. Incidentally he mentioned that it would be desirable to have a word more philologically correct than "appendicitis."

Mr. FIRMIN CUTHBERT (Gloucester) mentioned a case in which a subphrenic abscess was drained. The patient had had the symptoms of gastric ulcer five years previously. In that case the hyper-resonance over the abscess was well marked.

Mr. R. C. CHICKEN (Nottingham) described two very interesting cases in which dulness in the left hypochondrium was caused by extreme thickening of the pericardium. In one of these there was an abscess under the diaphragm with a very tortuous sinus.

Professor LENNANDER (Upsala) mentioned a case of a man who received a severe blow on the right side from a carriage. The liver was pushed down by a liquid collection between the diaphragm and the liver; this was evacuated by an incision in the loin and it was found that the liver was torn. The fluid was found to be a mixture of blood, pus, and bile. The man recovered.

Mr. NOBLE SMITH (London) described two cases in which the subdiaphragmatic abscess was the result of caries of the spine.

Mr. GODLEE, in reply, expressed the opinion that many cases of so-called metastasis were really cases of direct extension of sepsis. He doubted the value of the smell in the diagnosis of these abscesses.

OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, AUGUST 1ST.

After a few introductory remarks by the President of the Section, Dr. W. S. A. GRIFFITH (London), the first discussion on

Puerperal Fever in Relation to Notification

was opened by Dr. BERRY HART (Edinburgh). He recognised three forms of puerperal fever—viz. (1) the acute form associated usually either with serious laceration or ruptures of the genital tract, or with retention of portions of the placenta or membranes; (2) the lymphatic form; and (3) the venous form. As to the first form the difficulties of the labour would probably put the medical attendant on his guard. The second form was the most frequent, presenting the characteristic features of rigors and rapid pulse, high temperature, and in short the typical picture of sapræmia. The third or venous form was the most difficult to diagnose, inasmuch as it was simulated by typhoid fever, drain infection, &c. As to the "drain poison" so ably advocated by Dr. Playfair as a cause of puerperal pyrexia, he could only regard it as "not proven." Cases should be notified as puerperal fever where they had the clinical features of a general or threatened general pyæmia; sapræmic conditions, and localised septic pelvic conditions need not be notified. These definitions would, he hoped, meet the first of the objections made to notification—viz., the difficulty of definition of puerperal fever. Two other objections were met with—viz., the risk of misleading statistics due to errors in diagnosis, and the supposed unwillingness of practitioners to notify cases likely to end fatally. Of the first of these little was to be said, but as to the last there was no doubt that the notification of puerperal fever was always disagreeable to the practitioner, and yet on looking over the statistics of large towns, like Sheffield, London, and Leeds, he felt sure that notification was conscientiously carried out, since the notified cases considerably exceeded the number of actual deaths. The advantages of notification were, first, that it supplied information as to the frequency of this condition and of its tendency to increase or decrease; secondly, that it would help in prevention by putting the medical officer on the track of careless midwives or nurses. But notification was of little value unless accompanied by provision of hospital accommodation and isolation for bad cases. Proper laboratory equipment of such a hospital would be essential.

Dr. W. J. SMYLY (Dublin) said that it would be very important to know the extent of the mortality from puerperal fever in private practice; but this was a matter of great difficulty. As a matter of fact, the total returns of mortality in childbirth were of more scientific importance than the cases notified as "puerperal fever," for the latter returns were apt to be vitiated by variations in definition. In the Registrar-General's returns there were three classes of deaths reported: (*a*) deaths from metria; (*b*) deaths from accidents in childbirth; and (*c*) deaths due to causes not directly connected with childbirth. The greatest difference of opinion would be found in relation to the third group, because cases reported as due to rheumatic fever, typhoid fever,, scarlet fever, &c., after parturition might well be considered as being really, in some instances, cases of puerperal fever. The term puerperal fever was an anachronism; there was no such thing as a specific "puerperal fever," since fever after childbirth was merely a form of sepsis. The great difficulty was to know which cases should be notified. Dr. Berry Hart had said that cases of general infection should be notified but that it was not necessary in the case of local infection. But why not? Was not local infection also apt to be dangerous as a source of infection? And then why should they stop at puerperal sepsis? Why not notify all cases of sepsis occurring after surgical operations. As a matter of scientific value notification did not promise much, but as a matter of prevention of puerperal fever it might be of some value by inducing greater care and acting as a check. The popular view of puerperal fever was very different from the scientific one. According to the former it consisted in a kind of malign influence which became attached to a medical man, causing him to carry infection to every woman he attended; consequently notification would in many cases mean great injury to medical practitioners, if the words "puerperal fever" were used. It would be better to use the simple word "septicæmia."

Dr. JOHN CAMPBELL (Belfast) also thought that notification of puerperal fever as such would, in the present state of public opinion, lead medical men into great trouble with their patients and their friends, for the popular view was that puerperal fever was due to the fault of the medical man or the nurse. Consequently, while notification would be a good measure some means should be taken to safeguard the practitioners. His own view was that medical men were responsible for puerperal fever in only a small proportion of cases; the infection being generally conveyed by midwives. He knew of a case where a medical man attended a woman, using all possible precautions, yet she contracted puerperal fever. Three months later the medical man found that the daughter of the midwife was sufferiug from gonorrhœal ophthalmia, and that at the time of the confinement the midwife, who had made several examinations of the patient, was douching her daughter for gonorrhœal vaginitis. He believed that in a fair proportion of cases puerperal fever was due to antecedent conditions in the patient herself—e.g., gonorrhœa contracted before delivery. One important point in connexion with notification would be greater control of midwives and the education of the public.

Dr. ROBERT BOXALL (London) joined issue with Dr. Campbell in regarding the disease as at all likely to arise from disease pre-existing in the patient herself. This at least was the conviction forced upon him by the results at the General Lying-in Hospital where no case of sepsis had arisen during the last 12 years. Owing to the difficulty in deciding what should or should not be included under the term "puerperal fever" he agreed with Dr. Smyly that all cases of septicæmia, whether local or general, should be notified, for a mild form in one patient might be quite capable of setting up a violent form in another.

Dr. A. V. MACAN (Dublin) said that public notification of puerperal fever appeared to him to be out of the question until it became the rule of the profession to tell the patient and her friends when the case was one of puerperal fever. It was well known that at present this was usually not done. The use of notification generally was either for the good of the patient herself or to prevent the spread of the disease to others. The first object could hardly be hoped for in the case of puerperal fever, for unless the patient were removed from the charge of her medical attendant, no change could be made in the treatment or surroundings. As to the second object, if the practitioner were acquainted with modern antiseptics, he would not require notification to prevent the spread of the disease, and unless they had compulsory powers over midwives they could not compel them to cease practice. The great *desideratum* at present

was the better training of midwives. He believed that at the present time it was the rarest thing to find a trained midwife in country workhouses and country districts in general. As to auto-infection, while quite believing in its occurrence, he regarded it as so exceedingly rare as to have no practical influence on the percentage of puerperal mortality. In his opinion the first step should be to train both medical men and midwives more thoroughly, and not to adopt compulsory notification.

Professor J. W. BYERS (Belfast) pointed out that the great argument in favour of notification was that by its means the prevention of the disease might be hoped for. The definition of puerperal fever was a very difficult matter; but on the whole Dr. Berry Hart's broad definition might be accepted. Bacteriological examination was of great value in forming a diagnosis. Dr. Campbell had said that cases of auto-infection formed a large proportion of cases, but this was not his own view; on the contrary, he thought that they were of comparatively rare occurrence, as was shown by the statistics of lying-in hospitals and by the fact that the majority of cases of puerperal fever were met with in primiparæ, and that patients who were not examined vaginally hardly ever contracted puerperal fever. The mortality from this disease might be diminished, first, by teaching students and midwives the importance of abdominal examination; secondly, notification, for this would teach all concerned, on reflection, that in the great majority of cases the disease could be prevented.

Mr. JAMES GREEN (Portsmouth) asked what degree of pyrexia and what period of its onset after delivery would mark a case as a suitable one for notification. His own view was that a temperature under 100° F. would not need certifying, nor would a case coming on a week or more after delivery. As to personal asepsis on the part of the medical attendant, he found absolute certainty very difficult to secure.

Dr. R. BRUMMITT (South Australia) spoke of the conditions that existed in that colony, where the responsibility of notification rested with the medical attendant. Any statistics of cases of notification were of little value because of the differences of opinion as to what constituted puerperal fever.

Mr. J. H. TARGETT (London) thought that the object of notification should be the provision of proper nursing and treatment of the affected case, and if necessary its removal to an infirmary when the circumstances of the patient required it. In his teaching of the students he always impressed upon them the importance of the medical attendant taking upon himself the responsibility in every case of puerperal fever.

Dr. MICHAEL BEVERLEY (Norwich) considered that the main reason for the notification of puerperal fever was that it was a preventable disease and that notification would be the best means of stamping it out.

Dr. ARTHUR HELME (Manchester) took exception to Mr. Targett's attitude in instructing the students that when puerperal fever developed the student and the nurse were responsible. It had been so persistently explained to the public that in the matter of puerperal fever the practitioner was the sole and blameworthy cause that at the present moment in many districts to tell the friends that the patient had puerperal fever would permanently injure the practitioner. Whilst it was true that in most cases puerperal fever was due to infection from without it was equally true that in a large number of cases the source of infection was within the patient herself, hence if notification was to be adopted it was important that the erroneous popular view that in every case of puerperal fever the practitioner in attendance was practically a criminal should be combated.

Dr. HENRY BRIGGS (Liverpool) pointed out that puerperal fever should be regarded as surgical fever and that the modes of prevention of the one and of the other were identical. Much in the success of treatment depended upon early diagnosis, and if this were attended to notification was unnecessary. He advocated the provision of isolation wards as a supplement to notification.

The PRESIDENT considered that in the matter of puerperal fever, the only course open to the medical practitioner was to be candid with the patient's friends. He could not suppose that, as some of the speakers apprehended, the practice of the medical attendant would be seriously affected by such a course; every man who had done his work conscientiously would surely receive sufficient support from his patients to avert such dire consequences of a single unfortunate case. He read an extract from a communication from the Local Government Board pointing out that "the object to be attained in so far as preventive medicine is concerned, is to bring to the knowledge of the sanitary authority all those conditions which, supervening upon parturition, are communicable from one parturient woman to another. He also quoted the statement of a medical officer of health that his experience of notification had been disappointing, inasmuch as the deaths from puerperal fever in one or two years had been in excess of the notifications in his district; and that except for disinfection of bedding at the end of a case, the intervention of the medical officer of health was seldom necessary.

After a brief reply by Dr. BERRY HART, the following motion was proposed by Dr. BOXALL, seconded by Dr. BEVERLEY, and carried *nem. con.*

That it be a recommendation to Council that in the opinion of this meeting it is desirable that notification of puerperal fever (septicæmia) should be adopted generally.

STATE MEDICINE.

WEDNESDAY, AUGUST 1ST.

Dr. J. C. THRESH, medical officer of health to the Essex County Council and Lecturer on Public Health at the London Hospital Medical College, delivered a

Presidential Address

entitled Some Problems in Rural Sanitation. He said: One of the most interesting problems which has engaged the attention of scientists during recent years is that of the period for which man will continue to live upon this earth. There is a general consensus of opinion that a time will come when the earth will cease to be habitable, but there is a wide divergency with reference to the length of the period which will elapse before the human race disappears. There are those who think that some great catastrophe may terminate our existence at an early period, others calculate that we are using up the available oxygen in the atmosphere so rapidly that in the course of two or three centuries there will not be sufficient left to support life. At the opposite extreme we have those who teach that man may continue to inhabit the earth for the millions of years which will elapse before the cooling process solidifies all the water on the globe. These speculations, however interesting, have little bearing upon public health, but there are other questions somewhat analogous in character which sanitarians will have seriously to consider. One of the most important is the continued increase of population, an increase almost exclusively confined to towns and cities. The effect of over-population is well exemplified in the two countries in which the population has attained its maximum density, India and China. The result is periodic famines, generally associated with pestilence in some form, affecting wide areas and millions of people. The earth's population is increasing steadily and in certain countries with great and continuously increasing rapidity. The production of food cannot for any very lengthened period keep pace with the increase of population, and it may be that famine and disease will more and more frequently occur and keep down the population within the limit of the available food supply. The growth of the large manufacturing centres with the influx of rural labourers into towns, and the general neglect of purely agricultural pursuits, must in this country produce some marked effect. That this effect will conduce neither to increased health nor to longevity can scarcely be denied; hence it is a result which we must deplore. The country has already reached a condition in which the population far exceeds that which can be fed by its produce, and the condition is being aggravated year by year by the increasing population and continuous neglect of agriculture, and I am afraid will continue until we receive a rude awakening, an awakening which in all probability will stagger humanity.

Our purely rural population is slowly decreasing, our urban population is rapidly increasing: therefore year by year the feeding problem becomes more serious. This is a fact so well recognised that its very familiarity is producing contempt. It is well, however, that we should from time to time be reminded of the fate upon which we appear to be almost blindly rushing. Sanitary improvements unfortunately tend only to aggravate the evil and hasten on the day of reckoning. So much attention has been devoted to urban sanitation that the town dweller enjoys now many

advantages not possessed by those who remain in the country, advantages which tend to prolong life, increase health, and, generally speaking, make life better worth living. For example, in most of our towns every house is efficiently drained and abundantly supplied with pure water, rendering it possible, with the minimum of trouble, to keep a house and its surroundings sweet and clean and therefore healthy. In our villages and rural districts nuisances from the improper disposal of filth abound on every side and the water-supplies too often are unsatisfactory in quality as well as in quantity. Land is going out of cultivation and decreasing in value, yet it is often impossible to obtain a small quantity to effect sanitary improvements. Let a plot be required in order to provide cottages with ground upon which to dispose of the slops and house refuse, or for the erection of better houses for the labourer, or for the erection of an isolation hospital, and it is often almost impossible to obtain it. Land-owners refuse to sell small areas for such purposes, yet, in my county at least, farms are sold at ridiculously low prices and the speculator who purchases, recognising the demand for small plots, promptly cuts up the farms and sells the land at an enormous profit. The dog-in-the-manger policy so common amongst land-owners and their agents I cannot account for, but it is a fact which is well recognised and deplored. How to bring back people to the land is one of the greatest problems of the age. It is far too large a subject for me to dwell upon, but I am convinced that one of the chief requirements for restoring prosperity to our rural districts is increased facilities for acquiring small areas of land for sanitary improvements. With a sufficiency of land adjoining or near each house the necessity for sewers in most of our rural districts would be avoided, though in compact villages urban in character drains and sewers will still remain a necessity. The supply of water to our cottages is even a greater difficulty. Sanitary authorities are not only averse to the expenditure necessary to provide a public supply, but too often also averse to causing landlords to provide such a supply when it can be done at what is defined by Act of Parliament as a reasonable rate. Another very important requirement, I might almost say the vitally important requirement, is decent cottages for our rural labourers. Many Acts of Parliament have been passed having for their object the better housing of the working classes. Their utility in rural districts has been practically *nil*. We shall welcome the discussion on this subject, which will be opened by my friend Dr. Tew at one of the meetings of this section. The effect of the present defective accommodation upon the mental, physical, and moral well-being of the inhabitants is too well known to need repetition. The housing problem is of importance not only to the rural labourer but to the whole country, and should be treated as a national problem. My apology, if any is needed, for touching upon these questions relating to rural sanitation in my opening address is that we are meeting in a large agricultural centre, in the centre of a group of rural counties in which these subjects are of the deepest interest, and that I, as medical officer of health of one of these counties, am myself more particularly interested in their study and am desirous of doing what little I can towards improving their sanitary condition and bringing about a new era of prosperity.

Rate-supported Sanatoria for Consumption.

Dr. NATHAN RAW (Liverpool) read a paper on this subject in which he dealt specially with household infection. Phthisis was essentially a chronic disease that could not be stamped out by legislative action. The education of the public was a necessary preliminary. From the facts of the case the consumptive poor would have to be cared for at the expense of the rates. Existing Poor-law institutions were unfitted for the treatment of such cases. The Liverpool and Toxteth Unions formed a joint tuberculosis committee and secured a site upon the Dee at an elevation of 650 feet to be used for early curative cases only. Fresh air and sun were the only cures known at present. Notification and free disinfection were desirable. The erection of public sanatoria was mainly one of municipal enterprise. Within a few years it would probably be difficult for a consumptive to obtain employment.

Dr. COOPER PATTIN (Norwich), Dr. ALFRED HILL (Birmingham), Dr. D. OLDFIELD (London), Dr. J. GROVES (Carisbrooke), Dr. H. PECK (Chesterfield), Dr. GRÜNBAUM (Liverpool) Dr. C. MACFIE (Bolton), and Dr. THRESH (Chelmsford) discussed the paper, and Dr. RAW replied.

PSYCHOLOGY.

WEDNESDAY, AUGUST 1ST.

Dr. PERCY SMITH (London) in his Presidential Address, referred to the subject of the Prevention of the Causes of Insanity. These comprised the marriage of the neuropathic and hereditary transmission, alcoholism, and syphilis. He pointed out the ways and means of prevention that should be brought into operation so that the recent and alarming increase of insanity should be checked.

A vote of thanks was proposed by Dr. MACDOWALL, seconded by Dr. SOUTAR, and carried unanimously.

Dr. MACNAUGHTON-JONES (London) opened a discussion on the Correlations between Insanity, Vice, and Crime, and pointed out the importance of coöperation between the alienist and the gynæcologist. The discussion was continued by Dr. SOUTAR, Dr. BERNARD O'CONNOR (London), Dr. WYNN WESTCOTT (London), Dr. PERCY SMITH, Dr. SEYMOUR TUKE (London), and Mr. CARDEW.—Dr. MACNAUGHTON-JONES then replied.

Dr. E. S. PASSMORE (London County Asylum, Banstead), read a paper on Epileptoid Mania or Psychic Mania, and instanced cases in support of the view that many cases regarded as recurrent non-epileptic mania were really epileptic in character.

The paper was discussed by Dr. OLDFIELD, Dr. LLOYD ANDRIEZEN (London), Dr. MACNAUGHTON-JONES, Dr. PERCY SMITH, Dr. SOUTAR, and Dr. MACDOWALL, and Dr. PASSMORE replied.

The meeting then adjourned till the next day.

PHYSIOLOGY.

WEDNESDAY, AUGUST 1ST.

The proceedings of this section opened with a debate initiated by the President, Dr. W. D. HALLIBURTON (London) upon the Formation and Excretion of Uric Acid in Health and Disease.

Dr. A. HAIG (London), Dr. T. H. MILROY (Edinburgh), Dr. F. G. HOPKINS (London), Dr. W. J. SMITH JEROME (Oxford), Dr. J. HADDON (Denholm), Dr. HARRY CAMPBELL (London), and Dr. R. J. ANDERSON (Galway), took part in the discussion.

Papers were then read by Dr. J. HERBERT PARSONS (London) upon the Dilatation of the Pupil from Cortical Stimulation, and by Professor E. WACE CARLIER (Edinburgh) upon Changes occurring in the Cells of the Newt's Stomach during and after Secretion.

PATHOLOGY.

WEDNESDAY, AUGUST 1ST.

Dr. E. E. KLEIN, Lecturer on General Anatomy and Physiology at the Medical School, St. Bartholomew's Hospital, delivered the following short

Presidential Address.

Pathology in its analysis of the nature of the tissue changes has been influenced, it is admitted, to a not inconsiderable degree by the progress made in bacteriology within the last two or three decades. Pathology no less than, and in no way different from, other biological sciences, intent on answering the "what," as also the "why," asks not merely what is the intimate nature of a particular change and aberration of a tissue or organ from its normal or physiological state, but also, and in a higher degree, why this change, and what its cause? Why a particular alteration in one, another in another instance? Microscopical and experimental analysis have both been active in discovering some fundamental facts, but have left numerous gaps in this study, and it is by the aid of bacteriology—since it became, thanks to the foundations laid by Koch, an exact science—that these gaps are being closed up, or at any rate that the manner and method are indicated by which these gaps may, and probably will, be filled up. The time at my disposal does not permit of more than illustrating these propositions by a few of the more striking examples.

1. *Inflammation.*—For more than a century inflammation, by the aid of the improved microscope and by experimental work which had occupied a host of active minds and of great experimentalists, was being analysed in all its elements—the part that the vascular system, that the tissues, that the nervous mechanism play in establishing the peculiar alterations constituting the phenomena of inflammation, suppuration, and

their sequelæ; thereby an enormous number of facts were brought to light, by which the understanding of these particular aberrations from, and return to, the normal conditions became clearer, or were believed to have become well understood. It is now admitted, however, that with the exception of traumatic, thermic, and chemical agencies, the chief, if not the sole, cause of the changes of the vascular apparatus and the surrounding tissues constituting inflammation, inclusive, of course, of suppuration, are micro-organisms, which either by their chemical activity—producing substances which exert a toxic action on the vascular system or the tissues, or both—or by the toxic nature of the protoplasm of the microbes themselves lead to the abnormal interaction between the vessels and the tissues, manifesting itself in the exudation of fluid and formed elements of the blood and the progressive or retrogressive changes of the tissue elements themselves. It is one of the best-proved acquisitions in bacteriology that many microbes, either when growing and multiplying outside or within the tissues, produce toxins which in the tissues set up the phenomena of inflammation either locally or generally. This applies not only to those microbes which are specially and in the narrower sense connected with suppuration and abscess—for example, various species of pyogenic staphylococci, streptococci, and bacilli—but also to other specific pathogenic microbes like the diphtheria bacillus, the tubercle bacillus, tetanus bacillus, and typhoid bacillus. Koch's tuberculin, the diphtheria toxin, and the toxins of many other microbes produced in the test tube and then injected into the tissues produce typical inflammation. The same has been shown of the dead protoplasm of many microbes—for example, tubercle bacillus, cholera vibrio, bacillus pestis, and others, as also of some ordinary saprophytes—namely, that the dead bodies of these microbes contain pyrogenic and pyogenic substances capable of producing typical inflammation. Another set of phenomena of which an explanation is supplied by bacteriology is one well known in the study of inflammation—that is, the greater or lesser number of leucocytes in some inflammatory foci. It is well known that while some inflammations are characterised by copious transudations with few leucocytes, others, on the other hand, are associated with copious accumulation of leucocytes, as in suppuration. The phenomenon of chemotaxis seems to offer a good explanation for these differences; that is to say, while some microbes or their toxins powerfully attract leucocytes from the blood and connective tissues, others have no such effect or possess even the reverse—namely, negative chemotaxis. In a similar manner Pfeiffer first classified the effects of chemical substances on lower organisms.

2. *Necrosis.*—The most valuable and earliest observations were those of Roux and Yersin, showing that the toxin produced by the diphtheria bacilli has a powerful necrotic action on the tissues. The further demonstration of the actual presence of the toxin in the diphtheritic membrane supplied at once the simplest and most feasible explanation of the necrotic condition of the mucous membrane in diphtheria—namely, the multiplication of the diphtheria bacilli at a particular locality—be it the fauces or larynx, or trachea or bronchi, or any other membrane—causes the production of the toxin, which in its turn causes the inflammation, and further the necrosis, of the membrane. But this action—namely, localised inflammations leading to gradually progressing necrosis of the tissue elements—is not peculiar to the diphtheria bacilli and their toxins, for it is almost a common character of many, if not most, pathogenic microbes; it is observed in connexion with almost all hitherto known pathogenic bacteria, tubercle, glanders, leprosy, pseudo-tubercle, pathogenic cocci, and bacilli of various kinds. It is this progressive necrosis of the tissue following the typical symptoms of inflammation—congestion, stasis, diapedesis, and emigration of leucocytes—which is observed, granted the necessary number and virulence, as the effect of the action of many pathogenic microbes; inasmuch as at a particular locality primary as well as secondary foci are found, so long as their multiplication proceeds and their toxins are being produced, and thus the necrosis of the tissue spreads into larger and larger areas. In non-microbic inflammations, on the other hand, this necrosis is local and circumscribed, being due to the direct action of the noxious agent—thermic, chemical, or traumatic—and its action is limited to the part actually attacked or its immediate surrounding. The necrosis itself appears in both series, however, of the same essential character—namely, coagulation of the protoplasm of the tissue cells, inclusive of the vessels themselves, and a gradual disintegration and destruction of the cells as also of the intercellular ground substance. These phenomena have been well observed in the case of a number of pathogenic microbes. Another not less important set of appearances associated with the necrotic change caused by bacteria is the secondary leucocytosis and suppuration; and for this the chemotactic action that the necrosed tissue exerts on leucocytes, attracting these for one reason or another, probably as scavengers and removers, offers a ready explanation.

3. *Specificity of cell secretions.*—Until recent years it was generally considered that a specificity of cell secretions was one of the fundamental phenomena of the physiological or normal tissues. Behring, Kitasato, Brieger, Roux, Ehrlich, and many others have, however, shown that under the activity of many pathogenic bacteria and their toxins in an affected body a curious and important series of secretions on the part of the cells of the tissues takes place which is as specific as those others associated with the normal life—I mean the production of specific antitoxins and the production of specific agglutinins. It was further shown that not only under the stimulation of the cells by bacteria and their toxins are those specific antitoxins secreted, but that organic substances like abrin, ricin, and venin are capable of stimulating the cells to a like production of specific antitoxin. Moreover, quite recently a further highly interesting series of facts have been brought to light—namely, that particular tissue taken from one animal body and introduced into another causes a specific reaction, showing itself in this, that the living cells of the latter produce under the particular stimulation substances specifically acting on the particular tissue that has caused the stimulation.

A discussion was then introduced by Dr. F. W. ANDREWES (London) upon

The Pathological Distribution of Bacillus Diphtheriæ and the Bacteriological Diagnosis of Diphtherial Infection.

Dr. ANDREWES pointed out that the bacteriological diagnosis of diphtheria was required for two purposes—for the purpose of clinical diagnosis and for strictly scientific purposes, such as the demonstration of the diphtheria bacillus in the throats of healthy persons. In the latter case a rather prolonged investigation, extending perhaps over many days, might be required before the identity of the bacillus could be satisfactorily established. For clinical purposes a diagnosis was required within 24 hours, and for his report the bacteriologist had to rely mainly on the microscopic appearance of the culture. This was not sufficient by itself for the positive identification of the bacillus, and the report sent to the physician merely meant that a bacillus morphologically resembling the diphtheria bacillus was present in the patient's throat. With that additional fact in his possession the physician must then consider the clinical features of the case and form his own diagnosis. Under the conditions in which the diagnosis was required it was impossible to place the onus of making a diagnosis on the bacteriologist without affording him sufficient time to complete his investigation.

In the discussion which followed the PRESIDENT, Professor MUIR, Mr. W. M. CROWFOOT (Beccles), Dr. LISTER, Dr. LAZARUS-BARLOW (London), took part, and the conclusions formulated by Dr. Andrewes were accepted by all the speakers.

Professor MUIR read a paper On a Case of Serious Anæmia and Purpura Associated with Great Deficiency in the Red Bone Marrow.

Mr. ROGER WILLIAMS (Clifton) read a paper On the Pathogenesis of Myoma of the Uterus, and Dr. JOHN EYRE read a communication On Nutrient Media of Standard Reaction.

The proceedings of the section were adjourned until the following day.

OPHTHALMOLOGY.

WEDNESDAY, AUGUST 1ST.

An opening address was delivered by the President of the Section, Dr. W. A. BRAILEY (London), upon the subject of Ocular Headaches, after which a paper was read by Mr. RICHARDSON CROSS (Bristol) upon the Treatment of Chronic Glaucoma, when a debate ensued in which Dr. J. HERN (Darlington), Mr. WORK DODD (London), Dr. K. A. GROSSMANN (Liverpool), Mr. G. A. BERRY (Edinburgh), and Mr. DEVEREUX MARSHALL (London) took part.

DISEASES OF CHILDREN.

WEDNESDAY, AUGUST 1ST.

The proceedings in this section were well attended. After a few brief introductory words from Dr. F. TAYLOR (London), the President, the first subject for debate, the Nature and Varieties of Pneumonia in Children, was introduced by Dr. NESTOR TIRARD (London). Dr. LORIMER HART (London), Dr. NICOLAYSEN (Christiania), and Dr. A. M. GOSSAGE (London), took part in an interesting debate which followed.

PHARMACOLOGY AND THERAPEUTICS.

WEDNESDAY, AUGUST 1ST.

Dr. WALTER G. SMITH, King's Professor of Materia Medical School of Physic, Trinity College, Dublin, and Physician to Sir P. Dun's Hospital, gave a short

Presidential Address

on the subject of the Teaching of Pharmacology. The rise and growth of the science of pharmacology, he said, which was founded by Bichat and Magendie early in the century, has made it plain that all correct appreciation of the mode of action of drugs must be based upon physiology and pathology. The new departure has gradually leavened our conceptions of therapeutics and renders the teaching of this branch alike more intelligible to the student and more satisfactory to the teacher. I well remember the time when attendance upon materia medica lectures was a dreary enough obligation, and the course was to students perhaps the least popular in the entire curriculum. Comparing the teaching of materia medica and therapeutics 30 years ago with the present time three features stand out prominently: (1) the retrogression of descriptive materia medica in its restricted meaning; (2) the establishment of special courses in practical pharmacy at the medical schools, conducted in suitable laboratories; and (3) the development of pharmacology in its present acceptation—that is, the scientific investigation of the modes of action of drugs. In regard to the place of pharmacology in the medical curriculum and the best mode of teaching medical students I heartily join with Dr. J. B. Bradbury (Address to Section of Pharmacology and Therapeutics, Portsmouth, 1899) in protesting against undue neglect of what may be termed old-fashioned materia medica—that is, description of the *essential* properties and chemical nature of drugs—so far as these elucidate the action of the remedy or its relations to prescribing. A modern course of lectures on materia medica should most certainly be founded on the bed-rock of pharmacology—that is, physiology; but there is still room—nay, I think, necessity—for practical demonstration of the physico-chemical properties of drugs, and we need not even be ashamed of inculcating the utility of some familiarity at least with the pages of the British Pharmacopœia which it is the fashion of some to despise or decry.

Thanks to the labours of physiologists and pharmacologists on the one hand and of organic chemists on the other hand, it is now possible, and even comparatively easy, to give an interesting and practically useful course of lectures on materia medica and therapeutics to medical students, but not earlier than their third year. I venture to affirm that it is entirely the fault of the lecturer and not of his subject if he does not succeed in quickening the dry bones of materia medica and in awakening and maintaining the lively attention of his class. With a little thought and trouble numerous simple experiments, chiefly chemical, can be shown in illustration of the more important physiological and therapeutical properties of drugs. General principles can be laid down, alliances pointed out, and broad features sketched which connect together large numbers of drugs, into the individual details of which it would be wearisome and a waste of time to enter. Take, for example, antipyretics and their mode of action; or the local action of astringents and caustics, experimentally illustrated by the reactions of various acids and metallic salts upon solution of albumin. Or, again, the group of "aromatic compounds" where it is possible to give a brief but comprehensive survey of the general chemical and physiological relations of the subdivisions of this great group—namely, hydrocarbons, phenolic compounds, acids, and nitrogen derivates (alkaloids, &c.). And in this aromatic group, which includes the antipyretic drugs, there is abundant opportunity for drawing attention to many interesting points in illustration of the connexion between physiological action and chemical constitution.

Since the properties and motions of molecules which determine physical properties depend upon the motions and properties of atoms which determine chemical reactions, the same common laws must govern both physical and chemical phenomena; and no one can doubt that the properties of the most complex compounds depend upon, and are intimately correlated with, the properties and configurations of the atoms and molecules of which the aggregates are built up. This fascinating subject, which received its impetus in Great Britain from the labours of Crum Brown and Fraser, has not escaped the attention of former speakers at meetings of this Association, for at the Brighton meeting of 1886 Sir T. Lauder Brunton delivered an attractive address on the Connexion between Chemical Constitution and Physiological Action; and Sir W. Broadbent upon more than one occasion (in 1890 and again in 1895) has likewise referred to this topic which he rightly esteems as one of fundamental significance. Bit by bit—here a little, there a little—we are gathering the kind of material which can best help us to gain insight into the principles of therapeutics. True, we may have to wait a good while before a stately edifice can be built up, but none the less does it hold true that the problems of therapeutics, and for that matter of all biology, are, at the root of things, essentially chemical or physico-chemical, in so far as we are at all able to interpret them or refer them to general laws. Within the last 15 years the remarkable and daring theories of Van't Hoff and his followers upon the nature of dilute solutions, based upon certain physical data—namely, osmotic pressure, alterations of the boiling-point and freezing-point—together with Arrhenius's hypothesis of ionic dissociation have largely engaged the attention of physicists and chemists. Nor have they failed to make their impress upon pharmacological investigations. The earliest reference I have noted in pharmacological work to Van't Hoff's important researches is contained in a paper by Hofmeister.[1] In the same journal[2] is a suggestive paper by Dreser, "Ueber Diurese und ihre Beeinflussung durch pharmakologische Mittel."

One word in conclusion. The flood tide of discovery of new synthetic chemical remedies has, together with a few treasures which have risen on its crest, also washed on shore much rubbish of a pseudo-scientific sort. Are we not daily worried with samples and with advertisements and circulars from eagerly competing firms announcing new drugs or novel combinations which I fancy are used chiefly by those who do not know how to employ the old ones? Scarcely are they advertised once before they are elbowed away by importunate new-comers. The advertisement is headed with an enigmatical name, standing over an appalling chemical formula, and probably ornamented with a structural or graphic diagram. All this is backed up by a plausible show of original experimental work and ends with a "full literature." In a pamphlet lately issued about some new-fangled preparations of iron 62 literary references were appended and a well-known and reputable drug firm advertised in a recent number of the *British Medical Journal* more than twenty of its special preparations, some of which probably most of us never heard of. And not only are we plagued with innumerable circulars which choke our waste-paper baskets, but we are tormented during our consulting hours at home by the visits of smooth-tongued touting agents of many of the large firms. This most objectionable practice is on the increase. It should, in my humble opinion, be stamped out by the medical profession, and I avail myself of this public opportunity to protest against it. For some time past I have made it an invariable rule, and given directions accordingly, that I will not receive or interview the agent or representative of any drug firm, no matter how famous. If by chance or sheer audacity one of these gentry does find his way into my consulting room he very speedily finds his way out again.

LARYNGOLOGY AND OTOLOGY.

WEDNESDAY, AUGUST 1ST.

Presidential Address.

The President of this section, Dr. SCANES SPICER, in his opening address, after welcoming those attending the

section and thanking those who had undertaken to introduce the discussions and offer papers for consideration, went on to say:—

Again, in 1900, we have a combined Section of Laryngology and Otology, in which arrangement, I think, the Council of the Association have acted wisely. Except when we meet in the largest centres, or on special occasions like international congresses, it is not easy to secure a sufficiently large attendance to make two sections profitable. Then, nearly all the present generation of specialists in throat, nose, and ear diseases practise all divisions, and there can be no doubt that the field of work and the chief questions of interest are the same to us all. Further, it appears to me that the sections of the British Medical Association annual meeting are intended not only for specialists but for the much larger number of practitioners who feel attracted to our subjects, and that we shall more effectually secure the diffusion of knowledge and interest by the consideration of broad questions common to both branches rather than of minute and unsettled problems peculiar to either laryngology or otology, more appropriately dealt with at the special societies and larger congresses.

In comparing the status of the specialist in the past with that of the specialist of to-day the President remarked upon the startling rapidity with which the evolution of the special study of diseases of the throat, nose, and ear had taken place, and predicted that it would not be long now before laryngology and otology would take full rank in all university and qualifying tests. He reminded his listeners that on the Continent and in America the universities had given to this specialty and its professors a recognition equal to that of any other branch of medicine or surgery. He then briefly reviewed the reasons for regarding nasal stenosis, obstruction, or insufficiency as a pre-eminent factor in the etiology of catarrhal processes of the throat, nose, and ear, and continuing, said:—

That the results of nasal obstruction are being gradually recognised is evidenced by the fact that it is now no uncommon thing to have cases of obstruction of the most diverse character sent for the adenoid operation in which the post-nasal adenoid hyperplasia element is absent or insignificant. This implies that the symptoms of obstruction as seen in one of its commonest forms are by some erroneously supposed to be due only to adenoids. It is by no means derogating from the claims of William Meyer to our gratitude if I suggest that in most cases of adenoids the post-nasal adenoid hyperplasia is only a part, and often a small part, in the pathological condition of the so-called adenoid child; that fractured and deflected bones and cartilages, turbinal enlargements, hypertrophied tonsils pushing up and growing up behind the soft palate, stunted nostrils, and even vaulted palate are often far more important features in the case at the time of examination than the post-nasal adenoid hyperplasia. The failure to recognise this or to act upon it is the cause of the unsatisfactory results which sometimes ensue if the practitioner has undertaken to bring about a cure by simply removing the adenoids. Hence the discredit and suspicion which have often surrounded the question of adenoid operations and an explanation, at the same time, of the most common factor in a recurrence. I believe the truth to be this: In many children with nasal obstruction no formal adenoid operation need be done with an anæsthetic—and its risks are not *négligeable* unless under special circumstances—if the other factors in the obstruction are attended to. I have no hesitation in estimating that many hundreds of adenoid operations are done unnecessarily in this country every year when adenoids are not present, or if present are only an insignificant element in the obstruction which depends mainly on other causes. The result of this is a complete absence of relief of the symptoms of obstruction or only a slight and temporary improvement by the adenoid operation. The question which we should put to ourselves is this: Is it the mere presence of the adenoids or the impeded breathing which leads to the arrested evolution evidenced by the so-called "adenoid physiognomy," the alar collapse, the stunted nostrils (persistence of infantile condition), the vaulted palate and crowded teeth, the "drawn" eyes, and the deformed chest? The answer can only be—the impeded respiration. This leads to imperfect use or disuse of the nasal channels, the structures adjacent have not the normal stimulus to grow excited by functional activity, and it is in the use or disuse of structures during growth and evolution that we shall find the master key to explain the normal or arrested evolution of the surrounding organs and structures. Hence child breathing is just as important as child feeding to bring about normal growth, and with insufficient supply of air through stenosed nostrils, or improperly prepared supply through the mouth come lessened vigour and weak breathing in addition to the developmental arrest.

It often happens that an operation for adenoids or nasal obstruction is regarded as the termination of the case and that it should be unnecessary to take any more special trouble. This idea should be most strongly combated. The operation is only the first step towards the child getting back into the right road. The track being clear it has now to be used and developed. Well-considered developmental and respiratory exercises for the expansion of the chest and the restoration of respiratory vigour, for the removal of articulation and resonance defects, hearing drill, correction of ocular defects, regulation of vaulted palate and crowded teeth, and numerous other defects may require careful attention if the child is to catch up his more fortunate companion who has not been hampered by years of obstruction. The operation removes the obstruction, but he has to overcome, often with difficulty, many of the results of the previous deficiency. In laying such stress on the influence of obstruction in producing hypertrophic or hyperplastic processes, it is not my wish even apparently to ignore other factors in the pathogeny of adenoids such as unresolved catarrhs, specific fevers, syphilis, struma, soil, climate, atmosphere, rickets, feeble breathing, and low vitality; but it is my deliberate opinion that if perfect nasal respiration be restored, in many cases, if the child is put under ordinary favourable hygienic conditions, almost miraculous improvement will follow; but all the care and attention directed against the other factors will prove unsatisfactory or fruitless if the nasal obstruction is ignored. Not that all cases of obstruction by any means require a formal operation if taken early. But it is far better to operate too early or for minimal obstruction than too late or not at all; but in order to prevent a long-standing obstruction during growth from imprinting itself indelibly upon the frame and features we must always have in view not only the removal of adenoids, but ensure the complete functional efficiency of the nasal channels as a whole.

In conclusion, I would remind you that prevention is better than cure, and that if in our field of work, as in others, we have knowledge of causative factors of disease, we can in many cases eliminate and prevent them. Just as in general medicine and surgery the highest achievement is the prevention of disease and deformity, so in our special areas of work we should aim at developing the prophylactic aspect of our subject and in diffusing the knowledge thereof broadcast. In this way, when a morbid process has been originated and detected, it can be corrected at an early stage. In this connexion I firmly believe that the greater recognition of the influence of nasal obstruction, in its earlier and slighter forms, in producing those catarrhal changes which extend to the ear, is destined to play a great part in the future in the prevention and arrest of deafness and other disorders in an early stage. As the constant dropping of water wears away the stone, though imperceptibly, so does the constant action of fall of air tension in a stenosed nostril make its result evident sooner or later. Physical laws are no more suspended in our field of work than in any other. It behoves us resolutely and firmly to apply scientific facts, and to concern ourselves no less with the beginnings of disease and its prevention than with the highest developments of special technique.

TROPICAL DISEASES.

WEDNESDAY, AUGUST 1ST.

Presidential Address.

Colonel KENNETH MACLEOD, I.M.S. (ret.), Professor of Clinical and Military Medicine at the Army Medical School, Netley, President of the section, gave an address defining the Scope and Aim of the Section's Work. He said: Since the last meeting of this section events have occurred which have emphasised the significance and enhanced the importance of its work. The war in South Africa has stimulated into vivid reality the unity and solidarity of the British Empire. The imperial idea implies not only a community of interests—social, commercial, and political—between the mother country and her colonies and dependencies, but also a community of suffering; and as tropical conditions and tropical diseases prevail in Greater Britain to such a large extent

the study of these, as they affect both the governing and the governed, has come to be recognised as a matter of vital and cardinal necessity. This has been fully acknowledged by the able Minister who presides over the colonies and who has realised more clearly than any of his predecessors the immense importance of inquiry and education as regards tropical pathology and hygiene. The Government of India has also awakened from its torpor and taken thought and action in the same direction by encouraging research, training men in bacteriological methods, establishing laboratories, appointing commissions, and promoting special investigations. A knowledge of the pathology and pathogenesis of disease must obviously precede and guide preventive and curative effort, and it cannot be too loudly proclaimed that this knowledge can only be obtained by systematic scientific research. The days of casual and statistical observations and dissertations have gone and it is now universally understood that nothing will avail for the solution of pathological problems except the undistracted work of trained agents provided with ample opportunities and appliances. The South African war has forced into prominent and painful attention two diseases which, although they cannot be called tropical diseases, manifest themselves with special severity as regards incidence and fatality under tropical conditions—namely, enteric fever and dysentery. That enteric fever existed in South Africa and was apt to prevail in South African towns and cantonments during the summer months was well known and its appearance among the troops engaged in this war was fully anticipated, but the excessive prevalence of the disease in a country and climate with a reputation for exceptional healthiness has come as an unpleasant surprise. No doubt the circumstances and exigencies of warfare are mainly responsible for the heavy tribute of sickness and death which enteric fever has levied. War shares with famine the malignant powers of enhancing the susceptibility to whatever infection happens to be present at the place and time. Enteric fever has been in grim evidence during recent wars on the Indian frontier and in the Egyptian Soudan; but malaria, cholera, yellow fever, and dysentery have on other occasions been stimulated into disastrous activity by war. So with famine: malarious disease, small-pox, diarrhœa, dysentery, and relapsing fever have attended or followed it, and at the present time cholera and plague are raging among the famine-stricken in India. The infection of enteric fever seems to be ubiquitous, portable, and peculiarly facile and subtle; and perhaps the most urgent question of the hour is how to mitigate its prevalence in the British army, in which in times of peace it causes one-third of the total mortality. It is important to note that a very marked contrast exists between the ordinary incidence and mortality of the disease in temperate and tropical or subtropical countries—in England and Canada on the one hand and in India and Egypt on the other. A similar contrast appears in the French army stationed in France and in Northern Africa. How much of this great excess is due to tropical conditions, topical and climatic, and how much to remediable sanitary defects, it is not easy to say, but side by side with the excessive suffering of the army in India we are confronted with the remarkable fact of the immunity of the native population. Whether a similar immunity exists among indigenous races and habitual residents in South Africa is an interesting question. Evidence seems to indicate that it is so. The native immunity in India, though not absolute, is undoubted; its cause has not been satisfactorily ascertained. It has been attributed to habituation to minute doses of the contagium, to protection conferred by attack during infancy and childhood, and to racial resistance acquired in the course of generations through both these influences. Some experiments by Freyer and others indicate that natives give positive reactions to Widal's test, but more extended and exact investigations on this point are desirable. It is quite certain that the immunity of natives is not due to superior sanitary conditions. Whether a similar immunity, temporary or permanent, can be engendered in European subjects by a process of inoculation such as has been devised by Professor Wright of Netley, and practised on a large scale among soldiers proceeding to the seat of war, is a question the reply to which is awaited with eager anxiety. Some figures obtained from Ladysmith have been published by Professor Wright which seem to show that some immunity is conferred by these inoculations, but though encouraging they are by no means demonstrative. Similar procedures for creating an immunity against cholera and plague initiated by Professor Haffkine have in India been attended with satisfactory results. But although a certain measure of preventive success has been obtained by these inoculations the employment of them appears at present to be practicable and useful only as an emergent expedient in the presence of a serious outbreak, and the prevention of cholera, plague, and enteric fever on a large scale must apparently be essayed on other lines and by other methods. Dysentery has been very rife in the South African army, but the disease has exhibited mostly a mild type and has been amenable to treatment. The persistence of plague in India and the appearance of the disease for the first time south of the equator—in Mauritius, South Africa, South America, and Australia—are events deserving of special notice. The disease has during its present prevalence confined itself mostly to warm and hot countries, and, though not exclusively a tropical disease, or apt in the tropics to be at its worst when conditions are most typically tropical, it appears to find in tropical countries and circumstances the most favouring environment. It is curious to remark that while in India natives appear to be readily susceptible to the infection of plague, Europeans, though not absolutely insusceptible, exhibit a comparative immunity—the reverse of what happens as regards enteric fever. This immunity is doubtless what I venture to call a sanitary immunity, due to a purer personal domestic and social life and perhaps to circumstances and habits rendering admission of infection less easy.

I trust that I have succeeded by these discursive observations in showing that recent events have expanded the scope and aim of our work in this section, and it seems to me fitting that we should at the commencement of our sectional labours remind ourselves of what these are. Our concern is not only with exclusively tropical diseases, many of them strangely named and imperfectly investigated and understood, which may be encountered and contracted in hot places where Europeans are compelled to reside for purposes of protection, administration, or commerce, and are not as a rule met with outside the tropics. More important are those diseases, originally or essentially tropical, which may be disseminated by intercourse with the tropics and may prevail for a time in extra-tropical localities in which they are not habitually present; and, finally, there are the diseases which are not specially tropical but which are liable to be aggravated in prevalence or severity by tropical conditions. These three classes represent a wide field of research, and, in addition, interesting questions arise as regards diseases which, common elsewhere, are rare or unknown in tropical countries. The field of study thus presented has its scientific and humanitarian aspects, and its cultivation has become an essential part of the business of imperial administration. It embraces not only acute infections and the sequelæ or constitutional incapacities resulting therefrom, but includes also those conditions affecting health and life which are vaguely designated as climatic, remediable only by adaptation, or which arise from sanitary defects or neglects capable of more easy amelioration. Hygienic improvements, personal, domestic, and social, have undoubtedly raised the standard of health and the value of life in the tropics, and residence and service in hot countries offer fewer and less formidable risks than they did in times past, but behind the question of individual impunity looms the question of colonisation or the continued vigour and vitality of the race when transplanted from temperate to torrid zones. The solution of these weighty problems constitutes the reason and purpose of our distinct sectional existence.

THE NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, AUGUST 1ST.

Presidential Address.

Inspector-General BELGRAVE NINNIS, M.D., R.N., took as the subject of his Presidential Address the Treatment of Wounded at Sea. It appears to me, he said, a happy omen that the inauguration of the Navy, Army, and Ambulance Section should take place at a time like the present, when the great war—now we trust nearly at an end—has directed special attention to its three sub-divisions—namely, medicine and surgery, in relation to the services, and ambulance in connexion with both, and likewise with civil life, particularly in large towns. A goodly supply of papers on these and kindred subjects will claim your attention, but I notice with

regret the absence of one on a subject which I consider would be well worth the trouble of writing—namely, on the means at the disposal of the naval medical officer for the treatment of the injured on board a man-of-war, more especially during an action. Now, before I enter upon this subject, I should like to make a few remarks on the light in which the naval medical officer is regarded by his fellows in civil life. Experience of the medical press, extending over a somewhat lengthened period, has left the impression on my mind that there is a belief amongst our brethren in civil life that the naval medical officers, taken as a class, are either behind the times professionally or are credited (from lack of zeal) with neglecting to avail themselves of modern discoveries, both in medicine and surgery, and that this is due in great measure to absence for lengthened periods from the schools. If I have rightly interpreted the meaning conveyed in the medical press, I trust that you will believe me when I state that you do us an injustice. It is true that from the very nature of his calling the naval medical officer is away at times for a period of three or four years; but, on the other hand, it should be borne in mind that there are sick in other countries besides Great Britain; and studying familiar diseases under different climatic conditions, or cholera, yellow fever, plague, and other diseases in countries where they are endemic, with the methods of treatment adopted by those who have lived the whole of their professional life in their midst, and modifications in some ordinary operations and substitution of new ones amongst the profession abroad, is surely worth something. Operations at foreign hospitals can always be attended, and practitioners and hospital surgeons are, in my experience, ever willing to answer questions and to show you their cases where possible. I have not said anything about his own patients, which, if his ship is a large one, supply him with a heterogeneous practice in addition to a capital operation occasionally. From what I have said it should be seen that the naval medical officer need not of necessity get rusty. I have not mentioned that in addition he has the medical press, foreign as well as English, or that on his return home provision has been made for seniors and juniors alike to pass through a post-graduate course at the metropolitan hospitals of Great Britain and Ireland.

Now let us return to the question of the means at the disposal of the naval medical officer for the treatment of the injured on board a man-of-war, more especially during an action. To grasp the situation fully it must be borne in mind that the essentials of a fighting ship may be said to comprise the largest percentage of armament, offensive and defensive, combined with capability of rapid motion and a steady platform. So far as our present knowledge goes these conditions can only be obtained at the expense of space; or, in other words, the more effective a fighting machine the ship is the less space is available for quarters and accommodation for the sick. Necessary as light and fresh air are to all of us, in the case of the sick on board ship it will easily be understood that this necessity is more urgent. But light and fresh air can only be obtained in sufficient quantity above the water-line, and to place the sick-quarters above the water-line, amidst the hurly-burly of a sea fight, traversed by projectiles and wrecked by exploding shells, is of course out of the question, even supposing that sufficient space could be spared. The alternative is treating the sick and injured below—which means a limited amount of fresh air and that almost invariably supplied by mechanical means—artificial light, rapidly deteriorating atmosphere, and the by no means unlikely intrusion of a torpedo or of the ram of a neighbouring ship. It will doubtless be said that this condition exists only during war-time and that under ordinary circumstances plenty of space could be found on deck. Sufficient accommodation is, as a matter of fact, already set apart for the treatment of the sick, with ample light and fresh air, cots, and other fittings of recent and constantly improving designs, and in some cases electric light; but it must be remembered that for the reasons previously mentioned these peace arrangements must be vacated in war-time. As permanent quarters for the sick on board a fighting ship, situated in such a position as to be freely supplied with fresh air and light, are practically an impossibility, it follows that the fitting up of apparatus and the means of utilising modern inventions are likewise practically impossible, and therefore the naval medical officer cannot avail himself of their use.

In fact, the naval medical officer is not to be judged by the ordinary standard. He works under great disadvantages. Take an ordinary operation. A moving patient on a moving table, a moving operator standing on a floor changing its slope laterally and fore and aft, assistants automatically altering their positions in relation to the patient in retaining the upright position or their equilibrium; tracheotomy by the light of a candle or lamp, the patient being in a cot, or possibly in a hammock; hernia to be operated on, possibly during bad weather, for it is the nature of things that on board ship accidents should most frequently occur when there is most motion and the decks are wet and slippery; fractures to be retained in position under the same adverse circumstances. As for lack of zeal a collection of the novel splints and appliances to be found on board ships on return from out-of-the-way foreign stations would testify not only to the zeal of the naval medical officer, but also to his resourcefulness, for, be it remembered, he cannot send into the next street for a second opinion or to the instrument-maker for special appliances.

In bringing these remarks to an end I may add that it is, I believe, intended in the future to supplement fleets and squadrons in war-time with hospital cruisers, not merely transports for the injured but veritable floating hospitals with steam power and fittings and appliances up to date. During an action these ships would keep out of range but sufficiently close to collect the wounded when the fight was over, and sailing under the regulations of the Geneva Convention would be free from molestation or capture.

THE ANNUAL MUSEUM.

Little fault could be found in regard to the space placed this year at the disposal of the exhibitors. Indeed, there was space enough left for a smoking-lounge, and seating accommodation was also provided between the stalls. The Public Hall in Westgate-street proved to be well adapted for the display of foods and food products, drugs, mineral waters, &c., and those thousand-and-one accessories with which the exhibitor decorates his stall with consummate effect and in a manner calculated best to attract the visitor's attention. Surgical appliances, aseptic furniture, and miscellaneous articles of more or less interest to medical men were assigned a place in the old museum rooms a few doors away from the Public Hall, and here, again, the exhibitors contrived to decorate the rooms in an artistic and striking fashion. The section relating to foods and drugs was decidedly on a smaller scale than the same section in the annual museum at Portsmouth last year; but there was enough to keep the practitioner's interest maintained from start to finish. The trade aspect of this section is unavoidable, but the museum sub-committee are to be congratulated on having selected only those subjects for exhibition which are strictly of medical interest. We cannot help thinking, however, that a considerable improvement would be effected and a certain substantial attraction added if a few demonstrations of a strictly scientific character could be held at the same time and in the same place. It is decidedly irksome to be constantly urged on all sides to consider new formulæ, to handle new contrivances, or to taste new food products. The round of inspection again would be much more comfortable to the visitor if the exhibitors were less pressing in urging the claims and merits of the various exhibits which sometimes is done in such a way as to come very close to the method of the tout. There is always a great deal to interest the medical man on the stalls of this annual exhibition, and he can soon become acquainted with the important advances in the preparation and style of drugs, in the elaboration of special foods, &c., without much assistance from the exhibitor, who is tempted too often to volunteer voluble information of a quite superfluous kind.

As on previous occasions we shall adopt the following classification of the exhibits, emphasising as far as possible those subjects of special novelty or which possess a special interest:—I., Drugs; II., Foods and Food Products; III., Sanitary Appliances, Disinfectants, &c.; IV., Surgical Instruments and Appliances; V., Mineral Waters, Beverages, &c.; VI., Publications; and VII., Miscellaneous.

I.—DRUGS.

In taking a general view of this important section of the museum two facts were noticeable—(1) that the tide of synthetics is steadily abating, and (2) that apparently little further departure has been made in regard to new administrative forms of medicaments. Certain organo-metallic preparations seem now to occupy the

position of novelty which some years ago was held by the coal-tar synthetics. It is easy enough for the organic chemist to elaborate new organic compounds, so abundant and suggestive are the materials at his beck and call; but some check, perhaps, has been placed on the successive production of these compounds by the action of the profession. Whilst recognising the value of many synthetics physicians have not failed to discountenance the indiscriminate placing upon the market of scores of complicated organic preparations the very multiplicity of which operates against determining their pharmacological value with that exactness which in the true interest of therapeutics is desirable. Some interesting derivatives of certain alkaloids were shown by exhibitors here and there, which are claimed to possess decided advantages over the original alkaloid. As examples we may quote the ethyl carbonate of quinine known as euquinine, and heroin the diacetic derivative of morphine. Again, there were some excellent illustrations of improvements in the pharmaceutical preparation of extracts and in the isolation from their respective plants of more or less definite and therapeutically active bodies which may be called "resinoids." A considerable amount of research has been undertaken in this direction in the "Merrell" laboratories of the Wm. S. Merrell Chemical Company, Cincinnati, Ohio (47, Wilson-street, Finsbury-square, London, E.C.), with encouraging results. Attention has been chiefly directed to retaining the active properties of the drugs and eliminating the inert or often injurious principles. Amongst these preparations we may mention podophyllin resin and the resin of rattle root or black cohosh known as macrotin and a much more efficient preparation than cimicifugin. The same firm showed some excellent hydrastia preparations and some pure specimens of salicylic acid crystals made from oil of winter-green. The crystals thus prepared are perfectly definite and well formed, a fact which in a measure testifies to the purity of the acid. An interesting derivative of oil of winter-green occurs in the form of "iodozen"—a true iodine compound of the oil of winter-green which possesses powerful antiseptic properties, rendering it an agreeable and effective substitute for iodoform. A very interesting collection of pharmaceutical chemicals was presented to view on the stall of Mr. E. Merck of Darmstadt (16, Jewry-street, London, E.C.). This firm has recently come prominently forward in the manufacture of perfectly pure preparations, including the alkaloids and the salts of organic acids, and the active principles of plant extracts and certain other rare principles. Perhaps the best examples of the interesting series of organo-metallic preparations which have been recently introduced into medicine occurred amongst the exhibits of Messrs. Burgoyne, Burbidges, and Company of 12 and 16, Coleman-street, London, E.C. We have already dealt with them in our analytical columns. Collargolum, for example, is described as a water-soluble metallic silver, and hyrgolum as water-soluble metallic hydrargyrum, both of which are more effective than the better-known salts of these respective metals. The exhibit also included citrate of silver, which is said to have been used with marked success in the treatment of wounds, and likewise lactate of silver. Messrs. C. J. Hewlett and Son, of 35 to 42, Charlotte-street, London, E.C., had a very well-arranged and attractive display of their special preparations. Worthy of mention as comparative novelties are bromipin, described as an organic compound of oil of sesame, and containing 10 per cent. of bromine, though there is no evidence of the presence of this element according to taste and smell. It appears to afford a means of administering bromine without giving rise to unpleasant effects. Naftalan has already been described in our analytical columns, but we may repeat that it is a product of the fractional distillation of Armenian naphtha and has been used as an analgesic and parasiticide. Cases are recorded of eczema and other skin diseases which have been benefited by the application of this interesting substance. Attention has recently been drawn to monsonia, the drug derived from *Monsonia ovata*, as a remedy for dysentery, and the seeds of the *Plantago isphagul* have been used for the same purpose. Preparations of these vegetable products are made by this firm. Their exhibit included also many excellent antiseptic preparations and a useful series of test-cabinets for clinical use. The introduction of "cacodyls" into medicine marks an interesting and important departure in the safe and effective administration of arsenic. Sodium cacodylate appears to be the best form for the purpose. It has been administered continuously in large doses in the treatment of phthisis and in diabetes. It favourably influences the processes of nutrition. Messrs. Gilbert, Kimpton, and Company of 19, St. Dunstan's-hill, London, E.C., showed examples both of the acid and of the sodium salt. Glass bulbs are made containing five-sixths of a grain and the so-called "arsycodile" pills 0·025 milligramme of sodium cacodylate. An iron cacodylate is also prepared especially for the treatment of chlorosis and anæmia. This interesting non-toxic organic salt of arsenic serves as a remarkable example of the therapeutic difference determined by molecular structure. The same acid and its sodium salt were exhibited on the well-stocked and attractive stall of Mr. W. Martindale of 10, New Cavendish-street, London, W. An interesting series of glass capsules was a feature of this exhibit, containing respectively amyl-nitrite, carbonised amyl-nitrite, chloroform, ethyl bromide and iodide, and isobutyl nitrite. Again should be mentioned the conveniently designed test-cases for clinical work. These included the portable urine test-case and a case containing bacteriological reagents necessary for the detection of tubercle bacilli, diphtheria bacilli, typhoid bacilli, and other micro-organisms. An interesting novelty on the stall of Messrs. Oppenheimer, Son, and Company, Limited, of 179, Queen Victoria-street, London, E.C., consisted of "cerettes." These are flexible tubes containing ointments and medicated soaps, each cerette holding sufficient for one application. The contents may be easily expressed from a cerette after the manner of a collapsible metal tube. While the cerette provides against the deterioration of its contents through contact with air, it avoids the possibility of metallic impurity. Ointments and soaps may thus be preserved unchanged and, moreover, are clean for the purpose of application. The exhibit included also some interesting applications of the palatinoids. Amongst these may be mentioned, as instances of the particular advantage of this administrative form of drug, palatinoids containing animal substances, palatinoids of liquids and of tinctures. Foremost amongst the pharmaceutical products shown on the stall of Messrs. Zimmer and Company, Frankfort-on-Maine, was a splendid specimen, in needle-shaped crystals, of euquinine. This is ethyl carbonate of quinine, behaving chemically as quinine, and pharmacologically also, with the advantage, it is stated, of being free from so many of the objectionable effects of quinine. Side by side with this interesting quinine substitute was eunatrol, a chemically pure oleate of sodium contained in chocolate-coated pills. This substance has been used with advantage in hepatic disorder and is said to stimulate the flow of bile and to assist the elimination of gall-stones. Another interesting compound shown by this firm was urosine, a quinate of lithia which is said to have a solvent effect upon uric acid concretions. It is used also favourably in gout. Validol (by the same firm) is a liquid compound of menthol and valerianic acid in which the objectionable properties of each constituent disappear. It has been employed as a restorative, stomachic, and anti-neuralgic, and has been prescribed also in hysteria with advantage. The Bayer Company, Limited, of 19, St. Dunstan's-hill, London, and Ebberfeld, have been very active during recent years in introducing new organic salts, and on the present occasion an excellent collection of skilfully prepared specimens were presented to view, which included trional, a hypnotic of some value, tannigen and tannopine, both intestinal astringents, salophen, valuable in the pyrexia of influenza, aspirin, the acetic ester of salicylic acid, giving all the therapeutic advantages of the acid without the disadvantages, heroin, the diacetic ester of morphia and its soluble salt, the hydrochloride, substituted with advantage for morphia. Lastly the interesting compound of protein with silver known as protargol is worthy of mention as an excellent substitute for nitrate of silver in diseases of the eye and for application as an antiseptic in gonorrhœa. It is easily soluble in water. Messrs. Parke, Davis, and Company of 111, Queen Victoria-street, London, E.C., exhibited such a complete series of their special preparations as to necessitate the occupation of two stalls. Amongst the drugs introduced comparatively recently should be mentioned chloretone, a hypnotic, antiseptic, and local anæsthetic which we have already described in our analytical columns. The exhibit included also standard serums, animal extracts, and a variety of drugs standardised by physiological tests upon animals and others standardised by chemical assay. "Kelpion" is the name of new stainless, non-irritant iodine ointment; the oil basis

is emollient and rapidly absorbs carrying with it the iodine. A few minutes after application the presence of iodine may be easily recognised in the saliva. It provides an excellent means of applying iodine in its well-known forms without producing objectionable effects. The preparation is exhibited by the Kelpion Company of Norgrove-buildings, 59A, Bishopsgate-street, London, E.C. Specimens of the pure oil of mustard were shown by Messrs. J. and J. Colman, Limited, of Norwich and 108, Cannon-street, London, E.C. The oil is well known as an application in the relief of rheumatic affections. Specially prepared sinapisms were also submitted to inspection, as was also a special mustard bran for use in poultices. A very tastefully displayed stall was that of Messrs. Wyleys, Limited, of Coventry. It contained a number of excellent administrative forms, powders, pellets, capsules, and cachets, whilst special drugs were contained in gelatin-coated pills which were oval in shape. This firm is evidently alive to the requirements of modern medicine. Kutnow's Improved Effervescent Carlsbad Powder has been approved by experience as one of the best preparations for the treatment of chronic constipation. It is identical in composition with the salts of the Carlsbad spring. It keeps well on account of having been carefully desiccated. The exhibit included an anti-asthmatic powder and cigarettes, the fumes from which are said to give relief and to have no objectionable action upon the heart, as is sometimes the case with lobelia and datura tatula.

Medical News.

VICTORIA UNIVERSITY.—At examinations held in July the following candidates were successful in the subjects indicated:—

SECOND EXAMINATION.

A. Anatomy and Physiology.—P. W. Ashmore, Yorkshire; C. H. Bromhall, Owens; Stanley Brown, University; Thomas Brown, Yorkshire; W. J. Cox, University College, Sheffield; J. A. Davenport, Owens; R. T. Dobson, University; W. P. Grant, Owens; H. S. Harling, Yorkshire; Rowland Heathcote, E. W. Henstock, Benjamin Herald, and G. R. Hitchin, Owens; E. F. Hoare, University; C. H. Hopwood and G. H. Leigh, Owens; Hugh McManus and William Rotheram, University; J. A. C. Roy, S. H. Ryan, W. F. Shaw, and J. M. Skinner, Owens; J. N. M. Sykes, I. C. Thorburn, and G. F. C. Walker, University; and M. S. Wood, Owens.

B. Materia Medica and Pharmacy.—R. A. H. Atkinson, J. B. Barnes, John Battersby, and A. N. Benson, Owens; J. P. Bligh, University; Alexander Boothroyd, Owens; Alan Boyle and W. E. Brierley, Yorkshire; Howard Buck and Laurence Clay, Owens; Richard Coates, Yorkshire; Reginald Collier and Thomas Coogan, Owens; Edward Cundall, Yorkshire; J. L. Falconer and J. P. Garlick, Owens; Ernest Gibson, University; Tom Glover, J. W. Hartley, and H. D. Haworth, Owens; S. L. Heald, Yorkshire; J. P. Henderson and Arthur Hendry, University; Benjamin Herald, Owens; W. E. Hewitt, University; Hubert Hodge and F. C. Hudson, Owens; C. A. Hughes, University; A. D. Hunt, Yorkshire; H. R. Hurter, University; Hamilton Irving, J. M. A. Jones, and W. H. Judson, Owens; E. W. Kemp, Yorkshire; George Laurence and J. T. Lloyd, University; T. W. Lonsdale, Owens; J. F. McCann, University; J. de V. Mather, Stuart Murray, R. T. A. Patchett, F. G. Pell-Ilderton, and Frank Robinson, Owens; William Rotheram, University; W. E. Rothwell, Owens; F. H. Salisbury, University; J. L. Schilling and W. G. Scott, Yorkshire; Harold Simms, J. M. Skinner, R. T. Slinger, and J. C. Smyth, Owens; J. W. Sowerbutts and Bertram Sluggitt, Yorkshire; R. H. Swindells, A. F. Thompson, A. M. Walker, Douglas Wardleworth, and E. M. Wilkins, Owens; Henry Woods, University; and A. R. Wright and William Wright, Owens.

FINAL EXAMINATION.

Part I.—E. M. Ashcroft, and F. H. S. Ashworth, Owens; Herbert Bates, University; S. W. Battle, Yorkshire; S. B. Brentnall, Owens; Henry Brown, Yorkshire; C. W. Budden, University; J. B. Cook, J. F. Corson, J. M. Cort, Alexander Cran, and E. N. Cunliffe, Owens; S. W. Davies, University; Tom Eastham, F. S. Fletcher, and Mercier Gamble, Owens; G. W. Gelderd, and V. J. Glover, University; P. H. Green, and J. W. Greenwood, Owens; Frederick Griffith, University; F. W. Harrowell, Yorkshire; A. G. Jackson, and R. E. Kelly, University; C. P. Lapage, H. F. Lee, and Charles Mackey, Owens; J. C. Mann, University; S. B. Mehta, Owens; J. S. W. Nuttall, and T. F. Pugh, University; P. A. H. Radcliffe, Yorkshire; H. H. Rayner, F. M. Rogers, F. R. Sawdon, and G. H. Shaw, Owens; Robert Smailes, Yorkshire; H. G. Tansley, Owens; A. R. Thompson, Yorkshire; George Unsworth, and H. C. Waterhouse, Owens; S. C. Wilkinson, Yorkshire; R. D. Willcocks, University; and B. M. Wilson, and J. G. Woolnam, Owens.

Part II.—Arthur Anderson, Owens; E. W. Anderton, Yorkshire; D. A. Ashton, Owens; Philip Benington and J. H. Billing, University; A. G. S. Broughton, Yorkshire; J. P. Brown, Owens; Robert Burnet, University; A. H. Capamagian, Daniel Cowin, and C. W. Crawshaw, Owens; J. L. Dimond,† University; F. H. Flack and C. R. Hall,* Owens; A. E. Horsfall, Yorkshire; E. C. Hulme, Owens; A. R. Jackson† and L. C. Johnson, University; Reginald Lawrence and C. H. Lee, Owens; S. F. Linton, University; B. C. Middleton and R. S. Nichol, Owens; A. S. Parkinson, Yorkshire; William Rigby, H. W. Russell, C. R. Schofield Herbert Terry, and A. G. Wilkins,† Owens; C. R. Willans, Yorkshire; and P. G. Williamson and W. A. B. Young, Owens.

* Awarded first-class honours. † Awarded second-class honours.

Diploma in Public Health.—J. J. Butterworth, M.B., Ch.B; F. J. H. Coutts, M.D.; A. S. Grünbaum; C. A. Hill; and W. F. Moore.

Sanitary Inspection Certificates.—W. Butler, Manchester Technical School; J. J. L. Clark, University; and A. Herringshaw, F. Wilkinson, and R. W. Willan, Manchester Technical School.

UNIVERSITY OF EDINBURGH.—On July 28th the following degrees were conferred:—

Degree of Doctor of Medicine.—Charles Crawford Aitken, Scotland, M.B., C.M.; Charles James Hill Aitken, Scotland, M.B., C.M.; ‡Hugh Llewellyn Apthorp, England, M.B., C.M.; ‡James Andrew Blair, Scotland, D.Sc., M.B., C.M.; ‡John Macdonald Brown, Scotland, M.B., C.M.; Alexander Brownlie, Scotland, M.B., C.M.; *Walter William Chipman, Canada, B.A., M.B., C.M. (*in absentiâ*); Frank‡ Herbert Aylen Clayton, England, M.B., C.M.; Frederick William Collinson, England, M.B., C.M.; ‡Horace Crankanthorp Colman, England, M.B., C.M.; William Craig, Scotland, M.B., C.M.; ‡Herbert William Crosse, England, M.B., C.M.; Arthur Dickson, Scotland, M.B., C.M.; †Charles Cromhall Easterbrook, England, M.A., M.B., C.M.; ‡Alexander Edington, Scotland, M.B., C.M. (*in absentiâ*); William Ernest Lloyd Elliott, Wales, M.B., C.M.; *David James Galloway, Scotland, M.B., C.M. (*in absentiâ*); William Alexander Gibb, Scotland, M.B., C.M.; Wilfred Ernest Gibbons, England, M.B., C.M.; ‡James Andrew Gibson, Scotland, M.B., C.M.; †Robert M'Lean Gibson, Scotland, M.B., C.M. (*in absentiâ*); Robert Wilson Gibson, England, M.B., C.M.; Thomas Gibson, Scotland, M.B., C.M.; ‡Harry Grey, Scotland, M.B., C.M.; George Pouncey Henderson, England, M.B., C.M.; †Thomas Alfred Hird, England, M.B., C.M.; Guy Bertram Hollings, England, M.B., Ch.B.; Edward Siddall Jackson, England, M.B., C.M.; Arthur Septimus Lawrence, South Africa, M.B., C.M. (*in absentiâ*); ‡William Duncan Lawrie England, M.B., C.M.; Henry James Ley, England, M.B., C.M.; ‡Peter Burden M'Nicol, Scotland, M.B., C.M.; ‡James Sackville Martin, Ireland, M.B., C.M.; George Victor Miller, England, M.B., C.M.; Ahmed Mirza, India, B.Sc., M.B., C.M. (*in absentiâ*); ‡Owen St. John Moses, Armenia, M.B., C.M.; ‡Bernard Ehrenfried Myers, New Zealand, M.B., C.M.; ‡James Nicoll, Scotland, M.B., C.M.; Harold Nuttall, England, M.A., M.B., C.M.; Ernest Stanley Nutting, England, M.B., C.M.; ‡Edward Lloyd Owen, Wales, M.B., C.M.; George Peterkin, England, M.B., C.M.; ‡James Coubro Potter, England, M.B., C.M.; Frank Grégoire Proudfoot, Scotland, M.A., M.B., C.M.; †Francis White Hope Robson, England, M.B., C.M.; David Richard Rowlands, Wales, M.B., C.M.; Gerald Alick Southwell Sander, France, M.B., C.M.; ‡James Duncan Slight, Scotland, M.A., M.B., Ch.B.; Alexander Campbell Smith, Scotland, M.B., C.M.; ‡John Nigel Stark, Scotland, M.B., C.M.; John Edward Thomas, Wales, M.B., C.M.; †Peter George Leeb-du Toit, South Africa, M.B., Ch.B.; and *David Waterson, Scotland, M.A., M.B., C.M.

* Awarded gold medal for thesis. † Highly commended for thesis. ‡ Commended for thesis.

Degrees of Bachelor in Medicine and Master in Surgery.—Maung Ba-Ket, Burma; John Brodie Boyd, Scotland; Oswald Arnold Gee, England; John Thomas Hurst, England; John Malcolm Jeffrey, Scotland; Robert Alexander MacKenzie Macleod, Scotland; §John Charles Mitchell, D.Sc., Scotland; Archibald Duncan Nimmo, Scotland; Robert Owen, Wales; and Miles Charles Carreston Seton, Scotland.

§ Passed with second-class honours.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Robert Cunningham Affleck, Scotland; Henry Alexander, Ireland; Thomas Hood Wilson Alexander, Scotland; Eliza Matthew Anderson, Scotland; Mary Scott Anderson, Scotland; Henry Ernest Arbuckle, Natal; Robert Andrew Jacomb Asbury, England; Bernard Hugh Stanley Aylward, England; Albert Augustus Ayton, Jamaica; Alexander James Baird, M.A., Scotland; Harvey Baird, Scotland; Simon Alexander Ballantyne, Scotland; Leonard Dieckmann Hamilton Baugh, Jamaica; John Henderson Bell, Scotland; Joseph Mitchell Benson, England; Hubert Bishop, Trinidad; ¶Arthur Branfoot Black, Scotland; John Southey Bostock, England; ¶Orlando Charnock Bradley, England; Laurence Percival Brassey, England; James M'Culloch Leigh Brown, M.A., Scotland; Launcelot Bruce, Scotland; Adam Brydon, Scotland; George Farnie Buist, Scotland; George Berkeley Butt, Ireland; John Profeit Campbell, Scotland; Malcolm Campbell, M.A., Scotland; Samuel Marcus Dill Campbell, Ireland; George Scott Carmichael, Scotland; Violet Alice Penrose Coghill, Ireland; John Craig, Scotland; Leonard Crossley, England; Horatius Bonar Dodds, Scotland; John Primrose Douglas, Scotland; Cyril Hartley Durrant, West Indies; William Eadie, England; Robert Sidney Ellis, Scotland; Cecil Henry Elmes, Ireland; Johannes Stefanus Enslin, South Africa; David Robert Evans, Wales; ¶Edward Ewart, Scotland; Drummond James Fergusson, England; Andrew Fleming, Scotland; Bernard Gilpin Forman, Scotland; Catherine Fraser, Scotland; Charles Fraser, M.A., Scotland; Alexander Frew, Scotland; ‖William Ernest Frost, Ireland; Yoshinobu Fukuda, Japan; James Stewart Geikie, Scotland; William Girdwood, South Africa; Arthur Evelyn Goldie, Jamaica; George Watson Guthrie, Scotland; George Henry Hanna, Jamaica; Frederick Hardie, Scotland; Norman Ernest Jasper Harding, England; Herbert Harris, England; Thomson Henderson, Scotland; Davis Heron, Ireland; Eleanor Hodson, England; Katie Welton Hogg, B.A., Australia; Henry John Hoile, M.A., Scotland; Lionel John Hood, Australia; William Hutchison, England; Francis Field Cunningham Jagger, England; Edward Bald Jamieson, Scotland; ¶James George Silver Jamieson, M.A., Scotland; James Crawford Kennedy, Scotland; Francis Kenneth Kerr, Scotland; Herbert Christian Keun, Straits Settlements; Servaas Meyer de Kock, South Africa; George Ross Laing, Scotland; ¶Langworthy Laurie, England; Robert Gerald Leach, England;

Charles George Stretton Leeds, England; George Herbert Lewis, Wales; Robert John M'Clelland, Ireland; Christopher Birdwood M'Conaghy, Ireland; ¶John Gordon M'Dougall, Scotland; Sara Lyle M'Elderry, Ireland; Elizabeth M'Elney, Ireland; Alexander Campbell Nicholson M'Hattie, Scotland; James Herbert M'Kee, Ireland; Alexander John MacKenzie, Scotland; Dundas Simpson MacKnight, Scotland; Robert Clephane Maclachlan, New Zealand; Harriet Joanna Campbell Maclaren, M.A., Scotland; Henry John M'Lean, New Zealand; Duncan Mackay MacLeod, Scotland; John M'Callum Anderson Macmillan, M.A., Scotland; Elizabeth Macrory, Ireland; ¶Arthur Anderson Martin, New Zealand; Harry Mason, England; Frederick Crichton Matthew, M.A., Scotland; Mary Jenny Menzies, England; Hugh Crichton Miller, M.A., Scotland; John Brownlee Milne, Scotland; Robert Macfarlane Mitchell, Scotland; Janet Ainslie Shiells Mouat, Scotland; James Munro, Scotland; Florizel de Lorme Myers, Jamaica; Horace Clulow Nixon, England; Caroline Elizabeth O'Connor, Ireland; James Cuthbertson Parker, Scotland; Norman Patterson, Scotland; Cuthbert Balfour Paul, Scotland; ‖John Pender, Scotland; Mary Churchill Pepper, England; John Boyd Primmer, Scotland; John Rowlands Prytherch, Wales; Samuel Rattray, Scotland; Percy Chambers Rayner, England; John Lawrence Rentoul, Ireland; Owen Lewellin Rhys, Wales; Catherine Mary Richardson, England; Lionel Charles Peel Ritchie, Scotland; Thomas Robert Robertson, Scotland; William Rogers, Wales (*in absentiâ*); ‖Robert Ainslie Ross, South Africa; William Charles Ross, Scotland; Arthur John Ryle, Wales; Laura Stewart Sandeman, Scotland; Richard Akiwande Savage, West Africa; Thomas Boyle Hill Scott, Ireland; William Sibbald Scott, Scotland; Alexander Kenneth Smith Shand, Scotland; Hubert Dunbar Shepherd, England; ¶Thomas Scott Shepherd, England; Samuel Ramsay Sibbald, Scotland; Frederic David Simpson, Scotland; William Sloss, Australia; Harry Oswald Smith, Scotland; Charles Buchanan Snow, B.A., B.Sc., New Zealand; Charles Edward Southon, India; Hugh Meredith Speirs, England; Arthur Dunbar Spence, Scotland; Eleanor Rosina Sproull, Ireland; Thomas Grainger Stewart, Scotland; Clement Percival Strong, India; Frederic Troughton Thompson, Scotland; John Thornhill, Ireland; John Hardwick Thornley, England; ¶Alexander Trotter, Scotland; George Reynolds Turner, England; Karl Hermann Heinrich Uffmann, India; ¶William Wallace, England; Andrew Gordon Watson, Scotland; Allan Stewart Watson, England; Norman Septimus Wells, Burma; George Duncan Whyte, England; Frank Morewood Wigg, Australia; Alexander Jeans Williamson, Scotland; Tasman John George Wilson, Tasmania; Albert Edward Bathurst Wood, England; ‖Arthur Murray Wood, Scotland; ¶Garnett Wright, England; John Harold Wrightson, England; and Johannes Cornelius Zuidmeer, Cape Colony.

‖ Passed with first-class honours. ¶ Passed with second-class honours.

The following scholarships, prizes, &c., have been awarded:—

Ettles Scholarship, Robert Ainslie Ross, M.B., Ch.B.; Beaney Prize in Anatomy and Surgery, George Scott Carmichael, M.B., Ch.B.; Freeland-Barbour Fellowship in Anatomy, Physiology, and Pathology, John Pender, M.B., Ch.B.; Allan Fellowship in Clinical Medicine and Clinical Surgery, George Scott Carmichael, M.B., Ch.B.; Mouat Scholarship in Practice of Physic, Edward Ewart, M.B., Ch.B.; Stark Scholarship in Clinical Medicine, George Lyon, M.B., Ch.B.; Gunning Victoria Jubilee Prize in Materia Medica, Ernest Francis Bashford, M.B., Ch.B.; Gunning Victoria Jubilee Prize in Obstetrics, Alfred Charles Sandstein, M.B., Ch.B.; Buchanan Scholarship in Gynæcology, Frederic David Simpson, M.B., Ch.B.; James Scott Scholarship in Midwifery, William Ernest Frost, M.B., Ch.B.; M'Cosh Graduates and Medical Bursaries, John Charles Mitchell, D.Sc., M.B., C.M.; and the Anderson Henry Prize in Botany, Cameron Robertson Gibson. The Cameron Prize in Therapeutics has been awarded to W. M. Haffkine, C.I.E., for his work in preventive inoculation for plague.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. R. Stern has been promoted to an Extraordinary Professorship of Internal Medicine. Dr. Paul Jensen has been recognised as *privat-docent* of Physiology.—*Chicago (Rush Medical College):* Dr. J. Loeb has been appointed Professor of Physiology in succession to Dr. Dodson.—*Freiburg (Baden):* Dr. Nagel, assistant to Professor Kries, has been recognised as *privat-docent* of Physiology.—*Greifswald:* Dr. Philipp Jung has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Heidelberg:* Dr. C. Jung, Professor of Odontology, has resigned. Dr. Karl Gegenbaur, Professor of Anatomy, is retiring.—*Kiel:* Dr. Hans Hensen has been recognised as *privat-docent* of Internal Medicine.—*Leipsic:* Dr. Sandor Kaestner, *privat-docent* of Anatomy, has been promoted to an Extraordinary Professorship.—*Munich:* Dr. Oscar Eversbusch of Erlangen has been offered the Professorship of Ophthalmology as successor to Dr. von Rothmund, who is retiring.—*Philadelphia (Polyclinic):* Dr. James Thorington has been appointed Professor of Ophthalmology.—*New York (Post-Graduate School):* Dr. Charles W. Allen has been appointed Assistant Professor of Dermatology.—*Strasburg:* Dr. Martin Benno, *privat-docent* of Pathology and Pathological Anatomy, and Dr. Dietrich Gerhardt—son of the well-known Professor Gerhardt—*privat-docent* of Internal Medicine, have been appointed Extraordinary Professors.—*Tubingen:* Dr. Ernst Schwalbe of Berlin has been recognised as *privat-docent* of Physiology. Dr. Sarwey, Assistant Physician in the Female Clinic has been accorded the rank and title of Extraordinary Professor.—*Würzburg:* Dr. Ludwig Medicus has been appointed to the Chair of Pharmacy and Pharmaceutical Chemistry.

SOUTH WALES AND MONMOUTHSHIRE SANITARY INSPECTORS' ASSOCIATION.—A meeting of this association was held at Cardiff on July 26th, under the presidency of Dr. W. Williams. Dr. Walford read an interesting paper upon the Work of Port Sanitary Authorities.

SUPERANNUATION ALLOWANCE.—On the resignation of Mr. George Rigden, M.R.C.S. Eng., after 63 years' service as surgeon to the Canterbury Dispensary, he has been granted by the committee an annuity of £200 per annum.

MEDICAL MAGISTRATES.—Mr. H. G. Button, M.R.C.S. Eng., of Junee, Mr. A. E. Cox, M.B. Edin., of Forbes, Mr. W. J. Munro, M.B., Ch.M. Edin., M.R.C.S. Eng., of Glebe, and Mr. H. Chesson, L.R.C.P. Lond., M.R.C.S. Eng., of Pittsworth, have been appointed Justices of the Peace for New South Wales or Queensland as the case may be.

PRESENTATIONS TO A MEDICAL MAN.—Mr. Frank A. Arnold, M.B. Lond., late resident surgeon of the Memorial Hospital, Buluwayo, on the occasion of his leaving the hospital, was presented by the nurses with a clock as a token of their high esteem and respect.—Dr. Arnold was also the recipient of a travelling toilet case from the orderlies of the hospital.

THE HOSPITALS OF ONTARIO.—The thirtieth annual report of the hospitals of the province of Ontario shows that there are now in operation in this province of 2,000,000 people 50 hospitals directly receiving Governmental aid annually from the revenues of the province. The number of sick treated in these various institutions during the past hospital year numbered 26,825, exclusive of the thousands known as outdoor patients who receive advice and medicine from time to time. The total expenditure for the year has approached 500,000 dols. Of this amount the Government contributes a little over one-quarter. In addition to this there are some 40 houses of refuge in the province, 31 orphan asylums, 4 homes for incurables, 3 convalescent homes, 18 county homes for the poor, and 2 Magdalen hospitals, having an aggregate of 10,000 inmates. A glance over the report shows the number of certain diseases treated in these hospitals; for instance, there were 527 cases of appendicitis, 321 being male and 206 female; hysteria, 47 males and 224 females; locomotor ataxia, 28 males and 3 females; glaucoma, 17 males and 17 females; gall-stones, 41 males and 43 females; diabetes mellitus, 42 males and 14 females; epithelial cancer, 112 males and 83 females; goitre, 7 males and 36 females. The Toronto General Hospital admitted 2986 patients during the year; 3388 were treated during the year, of whom 206 died. The revenue of this hospital was $76,633.13 and the expenditure $79,911.61.

METROPOLITAN HOSPITAL SUNDAY FUND.—A meeting of the Council of this Fund was held at the Mansion House on Monday, July 30th, Sir Sydney Waterlow being in the chair. The report of the committee of distribution for 1900, which stated that this year 199 institutions had made applications for grants from the funds at the Council's disposal and that the distribution of £46,492 to 140 hospitals, &c., and to 54 dispensaries was recommended, was adopted. For the second time Mr. George Herring has given £10,000 to the Fund. Sir Savile Crossley has made a donation of £500. The only matter of unusual interest upon which discussion took place was a reference to the state of affairs at the National Hospital for the Paralysed and Epileptic, Queen-square, a matter which we deal with elsewhere. Extraordinary pressure on our columns prevents us from detailing the awards this week.—The following were among the principal amounts received on July 31st at the Mansion House in aid of the Metropolitan Hospital Sunday Fund: Sir Savile Crossley, Bart., a further £500 (tenth donation); Westminster Abbey, £161; St. Stephen, Westbourne-park, £138; Willesden Presbyterian Church, £48; St. Matthew, Forest-gate, £20; Wanstead Friends' Meeting, £38; Catholic Apostolic Church, Chelsea, £40; St. Margaret's, Lee, and Boone's Chapel, £51; St. Margaret, Barking, £38; Barnes Parish Church, £25; All Saints', St. John's Wood, £40; St. Barnabas, Clapham-common, £32; Camden-road Baptist Chapel, £20; St. John's, Lensford, £22; St. Matthew, Ealing, £33. The total now

exceeds £49,500. This year's awards will probably be paid on or about August 10th.

THE LATE MR. W. L. HUGHES.—Mr. William Lewis Hughes died at his residence, Carmarthen, on July 17th, in his forty-eighth year. Mr. Hughes was the son of the late Mr. Hughes of Trebersed. He was educated at Llandovery Grammar School and received his medical education at the London Hospital Medical School, qualifying as M.R.C.S. Eng. and L.S.A. in 1875 and 1874 respectively. After filling resident hospital appointments in London he commenced practice in Carmarthen and held for several years the appointments of surgeon to the Carmarthen Infirmary and to Carmarthen Prison; he was also district medical officer to the Carmarthen Union and surgeon to the 1st Volunteer Battalion the Welsh Regiment. At the time of his death Mr. Hughes was consulting surgeon to the Carmarthen Infirmary and medical officer of health of the town. Mr. Hughes, who was very popular in Carmarthen, will be much missed there, and by his early death a familiar figure in the district has been removed.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JULY 26TH.

Arsenic Poisoning.

MR. TENNANT asked the Home Secretary whether an inquiry was held in 1899 into the nature of employment in the extraction of arsenic; whether he had received a report upon the subject and, if so, whether it would be laid upon the table of the House; and whether it was proposed to amend the existing special rules relating to this employment.—Sir MATTHEW WHITE RIDLEY replied: I instituted an inquiry last year with regard to the health of the persons employed in certain works for the reduction of arsenic in Devon and Cornwall. I have not yet received the final report on this inquiry, but I gather from an interim report made some time ago that it is not likely that the establishment of any new special rules in these works will be necessary.

The Local Government Board Vaccine Lymph.

Mr. THOMAS BAYLEY asked the President of the Local Government Board (1) whether he had received information of the bacterial impurity of the vaccine lymph now or recently supplied for vaccination; (2) whether he was aware that certain brands of lymph, including that supplied by the Local Government Board, had developed colonies of germs, rendering their use improper for vaccination; and (3) whether he would prohibit the use of such lymphs in vaccination until freedom from contamination by them might be ensured.—Mr. CHAPLIN: In reply to the first paragraph, I have received no information as to the bacterial impurity of the vaccine lymph now or recently supplied by the Local Government Board which renders its use improper for vaccination. The answer to the second and third paragraphs is in the negative.

The Use of Preservatives in Food.

Mr. LAMBERT asked the President of the Local Government Board if he could state when the Departmental Committee on the use of preservatives in food might be expected to report; whether he was aware that summonses were being now issued by local authorities for adding to Devonshire clotted cream a small quantity of boric acid solely as a preservative; and whether he would communicate to such local authorities the undesirability of proceeding with prosecutions on this point until the report of the Departmental Committee had been issued.—Mr. CHAPLIN replied: I am informed that some delay has been occasioned by a series of experiments the issue of which will not be known for some months yet, but the Committee hope to complete their report by the end of this year. I understand that some local authorities have recently instituted proceedings in cases such as those referred to in the question. The Local Government Board, however, have no power to prevent such proceedings being taken, and they could not undertake to interfere with the discretion of local authorities in the matter.

Famine Administration in India.

In introducing the Indian Budget, Lord GEORGE HAMILTON made a long and interesting statement on the famine and the steps which were taken by the Indian Government to alleviate its consequences. He explained that the affected area in this case is greater than in 1876 or in 1896. In the former year the affected area was 205,000 square miles with a population of 36,000,000 and in the latter 275,000 square miles with a population of 52,000,000, while this year the area is 420,000 square miles with a population of 62,000,000. On the subject of administration Lord GEORGE HAMILTON said: The conclusion at which I have arrived from a careful study of the famine of 1896-97 and from my previous experience of the famine of 1874 is that the first essential of successful famine administration is to get the people to come in early, when they are still in good physical condition. If that is done then it is easy enough, but if, on the other hand, from various reasons, the people will not come on the relief works until the last stage of exhaustion and inanition, their vitality is so low that it is almost beyond the powers of the authorities to revive them. They bring with them the germs of disease which they communicate to healthy persons. Almost all the criticisms which have been hostile to the administration of famine relief have been devoted to the conduct of famine affairs in the province of Gujarat, and the province has not been afflicted by famine or drought for nearly 100 years. The mortality in Gujarat has been exceptionally high. It has been a source of the greatest solicitude both to myself and the Viceroy. I have been in constant communication on the subject, but it is exceedingly difficult to put your finger on any error which has been made. The expenditure per unit there on relief is higher than in any other part of Bombay. The works there are more numerous, and the number of additional officers drafted there is higher than in any other part of Bombay. The collection of the land revenue has been almost infinitesimal. Undoubtedly the result, so far as mortality is concerned, is not satisfactory. Whenever operations are over it has been the practice to appoint a commission of inquiry to investigate the various methods adopted. We shall have recourse to this procedure when the famine is over, and I hope that the collection of facts and the expression of opinions may be of use to the officials of the locality in dealing with subsequent outbreaks.

FRIDAY, JULY 27TH.

Preservatives in Food.

Mr. LAMBERT asked the Attorney-General whether, as a Departmental Committee was now scientifically investigating the question of adding preservatives to food, and would report by the end of the year, he would send an intimation to all judicial authorities before whom any cases of adding preservatives to Devonshire cream might be brought, that it would be expedient to adjourn the proceedings until after the Departmental Committee has given its decision.—The ATTORNEY-GENERAL replied: I have no authority to interfere with the discretion of the judicial authorities in the way suggested in the question, and it would be most improper for me to attempt to do so.

Enteric Fever at Bloemfontein.

Sir WALTER FOSTER asked the First Lord of the Treasury if the South African Commission would be able to inquire into the insanitary conditions which led to the outbreak of enteric fever and the consequent overcrowding of the hospitals at Bloemfontein.—Mr. BALFOUR replied: It will rest with the Commission themselves to determine the scope of their reference, but my own impression is that if the insanitary condition was due to the neglect of the Medical Department it would undoubtedly come under the cognisance of the Commission. If, on the other hand, it was due to military necessities—as, for instance, to the insanitary condition of the camp following on Paardeberg—I imagine it would not come under the survey of the Commission; but that is my own personal impression. The Commission have full liberty to determine their own reference.

The Army Medical Department.

This department was discussed at considerable length while the House was in Committee of Supply on certain supplementary army estimates.—Sir WALTER FOSTER spoke of the establishment being dangerously low. He said that the Royal Army Medical Corps was so diminished in number and so starved as regards medical equipment that if a division were to be sent to China now, and a German division of the same strength went out, it would be found that the German force had probably 50 per cent. more medical officers than our force—a state of things which, he said, would be discreditable to this country. In Africa many hundreds of brave fellows had been lost from the want of proper medical appliances. In China they had the danger of a disease more serious and loathsome than enteric fever. Plague was prevalent in that empire at the present time, and our troops would be exposed to sanitary dangers of the gravest kind. He hoped, therefore, that the War Office would be wise enough to take precautions against an outbreak of plague, or, at all events, would endeavour to minimise its effects as much as possible. He urged the War Office to consider the establishment of a reserve medical corps. It would not be difficult, he said, to get a large number of young medical men to hold themselves in readiness under very easy conditions to accept service in case of national necessity. Another point urged by Sir Walter Foster was that the War Office, in addition to sending out civil surgeons to South Africa, ought to have sent out civil physicians, men of experience in connexion with the fever hospitals of this country and others.—Mr. BURDETT-COUTTS complained of the Army Medical Department having no transport of its own and in this connexion called attention to the important services rendered by the Irish Hospital and the New South Wales Field Hospital, both of which, he said, have their own transport. He insisted that the Royal Army Medical Corps had been undermanned in medical officers, orderlies, and nurses, and said this was the explanation of the sick and wounded not receiving proper attention. On the subject of nursing Mr. Burdett-Coutts said the objection of the department at home to female nurses ought to be overcome.—Sir JAMES FERGUSSON said he had good reason to believe that often there had been a deficiency of articles of first necessity in the field hospitals because the medical officers were afraid to demand the things they wanted, and he submitted that such a thing would not happen if medical officers had now, as they used to have, a settled position from which they could not be removed except for some grave failure of duty.—Dr. FARQUHARSON emphasised the need for sufficient transport for the department.—Mr. GEORGE WYNDHAM, in his reply for the War Office, spoke of the recent changes in the Royal Army Medical Corps. The present Secretary of State, he said, had proposed an establishment higher than had ever previously existed, and had not been able to obtain the number of officers he required. It was said that was because the rewards offered were not sufficient, but, acting on the advice of his military advisers, he had offered inducements to tempt young physicians to enter the Royal Army Medical Corps, and was it fair, when it was matter of common knowledge that the great medical colleges had boycotted the corps for years in order to exact concessions as to rank—was it fair, when their wishes had been met to attract competent physicians, to attack the Secretary of State because he had not sufficient officers to meet the situation? He would not dwell upon this, for the point had already been threshed out, and what was to be said on either side was well known to the Committee. In view of the efforts made to increase the Royal Army Medical Corps, in view of the fact that the establishment voted had not been reached, he was convinced that it was a question of organisation that demanded most careful attention and most strenuous effort at the end of the war. But they could not do this now. It was his belief that no increase of pay, no exaltation of rank could be expected in times of peace to attract a sufficient number of young, keen, and ambitious men to fill up the places that must be

filled up in time of war. A young medical man did not care to bury himself at Colchester or any other military centre to attend to a few hundred men suffering from the customary ailments of this country; he was ready to work for little or no remuneration in the slums of a great city or in the wards of a great hospital; he wanted the practice and experience necessary for a successful career. Therefore he had himself come to the conclusion that instead of striving to expand the Royal Army Medical Corps in time of peace to be adequate for the time of war, it would be necessary to make application to the great hospitals throughout the country to know in time of peace what men would be ready for service in time of war, or when there was large concentration of troops what men would be ready to come forward and work for the army as they would work in a great city in time of pestilence.

MONDAY, JULY 30TH.

Specialists for Invalided Officers.

Mr. BAINBRIDGE asked the Under Secretary of State for War whether, if an officer invalided home from the seat of war required the attention of specialists while in a military hospital in England, it was the rule that such advice had to be obtained and paid for by the officer himself or his relatives.—Mr. WYNDHAM replied: If the medical officer in charge of a patient is of opinion that the assistance of a specialist is required the cost would be borne by War Department funds.

Post-Graduate Course of Naval Medical Officers.

Dr. TANNER asked the First Lord of the Admiralty if the long-promised concession in favour of naval medical officers which was stated some months ago to be settled for immediate working, viz., giving medical officers the opportunity of visiting and studying at metropolitan hospitals for a period of from three to six months on their return from a long term of foreign service on full pay was now working; and, if so, how many officers have availed themselves of the concession.—Mr. GOSCHEN replied: Naval medical officers have for many years past been permitted to pass through a post-graduate course at metropolitan hospitals. The number allowed has by the regulations of Nov. 1st last been increased from seven to 20 annually, but owing to the despatch of a considerable number of naval medical officers to the Cape and China it has not yet been found possible to allow this increase to take effect.

WEDNESDAY, AUGUST 1ST.

Medical Acts Amendment Bill.

The Bill framed by the General Medical Council to strengthen it disciplinary powers and to enable the universities and other medical licensing bodies to withdraw their diplomas from practitioners whose names had been removed from the Medical Register for misconduct, was at this sitting of the House withdrawn. It was withdrawn presumably because there was no chance of getting it passed.

THE SOUTH AFRICAN COMMISSION.

Lord Justice Romer (President of the Commission), Dr. W. S. Church (President of the Royal College of Physicians of London), Professor D. J. Cunningham (Trinity College, Dublin), Mr. Frederick Harrison (General Manager of the London and North Western Railway), Sir David Richmond (ex-Lord Provost of Glasgow), and Major Tennant (secretary), commenced their labours on July 24th, when a statement (a summary of which was printed in our issue of July 28th) referring to the terms of reference and to the course to be adopted in taking evidence was made by the President. The Commission sat at Burlington Gardens.

Among the first witnesses called on were a number of departmental officials who detailed the routine followed in equipping the army. Surgeon-General JAMESON, Director-General of the Army Medical Department, said that immediately on the outbreak of war it was found that the medical *personnel* for two army corps and a cavalry brigade were exhausted. The number of medical officers in South Africa on Sept. 1st, 1899, was 32. During September 19 were sent out; in October, 138; in November, 102; in December, 38; in January, 1900, 44; in February, 48; in March, 50; in April, 10; in May, eight; and in June, 19; making a total of 508. This month 20 more were being sent out. The figures did not include the medical officers of colonial contingents.

Lieutenant-Colonel Johnston, Assistant Director A.M.S., and Major W. G. Macpherson, Deputy Assistant Director A.M.S., were also examined.

Lieutenant-Colonel J. S. COWANS, Deputy-Assistant Quartermaster-General, said that every requisition for extra medical men had been complied with.

General Sir HENRY BRACKENBURY, Director-General of Ordnance, said that in every case in which the goods were requisitioned they had been supplied, but they were dependent entirely on the trade for supplies and there was great difficulty in obtaining them in sufficient quantities. There had been no complaints of delay.

Colonel STEVENS, Principal Ordnance Officer, and Sir RALPH KNOX, Permanent Under-Secretary, having given evidence, Colonel STIRLING RYERSON, Canadian A.M.S., British Red Cross Commissioner, said he had gone round the hospitals every morning to see what was needed and to distribute medical comforts. No complaints had been made to him. He thought that the abolition of the office of sanitary officer had had much to do with the enteric fever epidemic.

WEDNESDAY, JULY 25TH.

The first witness called was the Rev. W. H. ORFORD who was in Bloemfontein from the entrance of the British troops until Lord Roberts left for the north. The hospital to which for two months he was attached, he said, was one of the worst in the district, because it was an old building. Everything was done to make it as comfortable as possible and there was no overcrowding. It was true that patients were lying on stretchers and mattresses and in some cases patients were not undressed for a fortnight. The patients in the hospital numbered 60, and the nursing was done by orderlies whom the men did not obey as they would female nurses. Everything was improved after the hospital had been in use a fortnight. In reply to a question with reference to other hospitals he said that he had never seen men lying in the mud.

Sir HOWARD VINCENT, M.P., described his visits to the hospitals in South Africa and expressed his belief that there was no real cause for complaint. There were some deficiencies but he could not speak too highly of the general arrangements.

Mr. WATSON CHEYNE, F.R.C.S. Eng., said that of course there had been over-crowding in the field hospitals, but that was the fault of equipment. He did not think the medical service was cut down to the same extent as the ordinary transport. At Paardeberg men were put under trees because there were few tents. Being out in the open did not affect the patients at all, for it was a beautiful time of the year. Personally he preferred being out in the open. The supply of dressings was rather short. The number of wounded was greater than expected or the ambulance service would not have been cut down, but the medical comforts were to be obtained. The only hardship was the long distance the men had to be sent back in ox wagons. The St. John Ambulance men were not good as orderlies owing to their want of training. At Driefontein it was quite impossible to collect the wounded for several hours owing to lack of ambulance accommodation. He was at Bloemfontein from March 13th till April 20th or 21st, during the greater part of which time the enteric fever epidemic was at its worst. He believed there were more cases in May. Within five days of reaching Bloemfontein Dr. Stevenson had arranged accommodation for 500 or 600 sick. There was a lack of beds but there was no particular fault to find with the houses used. Those who had no beds were accommodated on tressels. About April 20th they had had over 300 deaths in a 50-bed hospital. He thought there was a point which the medical members of the Commission might consider—namely, how far this epidemic was one of typhoid fever. The great majority of cases recovered in 10 days or a fortnight, and there were other characteristics which made him think that it was not typhoid fever. He had never heard that there were any men, sick or wounded, left without any covering at Bloemfontein, neither had he any reason to believe that men did not get the rations prescribed for them. The hospital accommodation at Kroonstad was bad. The orderlies tried to do their best, but many were untrained men, and if their best was not good that was another matter. No neglect of the sick and wounded came under his notice in any way. He was of opinion that an unnecessary amount of the time of the medical staff was taken up in administrative and clerical work.

A trooper in the City Imperial Volunteer Mounted Infantry was examined and said he fell sick at Sanna's Post and was treated with every possible kindness at Bloemfontein. The only discomfort he experienced was a ride in an ox wagon.

The Commission then adjourned its sittings in London till Monday, July 30th.

On Friday, July 27th, the Commissioners visited Netley and took the evidence of wounded and invalided soldiers from the front.

MONDAY, JULY 30TH.

The Special Commission appointed to inquire into the care and treatment of the sick and wounded during the South African campaign held another meeting on Monday, July 30th, at Burlington Gardens for the examination of witnesses. All the members of the Commission were present except Sir David Richmond.

Captain COUSENS of the City of London Imperial Volunteers was the first witness examined, and in reply to the CHAIRMAN (Lord Justice Romer) he said that when he got to Greenpoint camp he found that the men from the hospitals came there, and it was his habit to speak with them about their experiences, and he assured the Commission that he never heard the slightest complaint from them. On the way up country he fell sick from heart disease and debility just before Edenberg and along with six of his men he was taken to the Portland Hospital at Bloemfontein. He himself was in the hospital for eight days and he had not the slightest complaint to make about the treatment which he received. Everything was done that could be done. He saw no cause for complaint in any part of the hospital. He left the hospital on April 3rd and stayed in a hotel for six weeks during which time he visited No. 9 General Hospital. He visited this hospital twice and saw not the slightest cause for complaint. While at Bloemfontein he saw all sorts of men from his own and other regiments and he was sure that if they had had cause for complaint they would have mentioned it to him, but they made no complaint. He was sent down from Bloemfontein to Wynberg where also the arrangements were in his opinion excellent.

Mr. MURRAY GUTHRIE, M.P. for Bow and Bromley, was the next witness, and in answer to the CHAIRMAN he said that he went out to South Africa as secretary to the American Field Hospital, getting there in the beginning of February. He went first to Kimberley and afterwards left the hospital and went across to Bloemfontein, which place he reached about four days after Lord Roberts. The first hospital he saw in working order was at Driefontein after the battle at that place. There were about 430 cases in the field hospital when he saw it—nearly all wounded, but also some fever cases. He thought that the medical officers did everything that they possibly could do, but they seemed to be rather short of supplies, which was only natural in the circumstances. There were about 30 or 40 stretchers, and the rest of the men, of course, were lying on the ground. He spoke to many men and they quite realised that it was impossible for things to be otherwise; there was no grumbling. The worst cases were on stretchers and the remainder, Boers and British, were lying against the sides of wagons and the walls of houses. They were short of everything except meat, but this was unavoidable for it was the end of a march. One of the medical officers had been working for 13 hours on operations, and all of the medical men were working like slaves. The medical officers themselves had no better food than the wounded. He knew that because he dined with them and they had only the ordinary rations. A field hospital was not supposed to have 430 cases, and naturally they were short of everything—medical officers, orderlies, stretchers, tents, &c. He saw the convoy leaving. To the best of his recollection there were 15 ambulance wagons and some 30 or 40 bullock wagons, and the distance was about 30 miles over extremely rough roads. The weather was very hot and he remembered thinking that the wounded men would have a terrible journey. It would have been better if it had been possible to send them all in ambulance wagons. For himself he did not see any merit in the ambulance wagon except that it had a cover and the ox wagon had none. Of course, if a man lay down in an ambulance wagon he had a flat surface to lie upon whereas in an ox wagon there were ridges and rough places which could not be very agreeable to a wounded man. The medical officers said that they had very hard work, but they

were perfectly cheerful and they did their very best and made no complaints. All they were anxious about was to get the wounded down to Bloemfontein. This, of course, was a question of transport. If there had been sufficient transport the wounded would never have been left there, they would have gone straight into Bloemfontein. The ordinary ambulance wagons were not sent up, they were reduced by four-fifths, from 10 per cent. to 2 per cent. When he left Driefontein he went to Bloemfontein. At the latter place he resigned his appointment as secretary of the American Field Hospital and he occupied the office described in the army orders as "distributor of military comforts." His business was to receive and arrange for the transport of all goods sent out from England for the men at Bloemfontein. The appointment was given him by Lord Roberts and was under Government. He was at the railway station all day long and had an office there and a staff. He was generally there from six in the morning till at least six in the evening with intervals for meals. By-and-by things got slack in his office and when he had leisure he went about the hospitals and he supposed that he visited every one of the hospitals at Bloemfontein. At first he went casually, say to see an official or a patient he knew, but towards the end of April and the beginning of May he took special pains to visit the hospitals because he had heard a good deal about what was going on in them. The first hospital he saw was the Imperial Yeomanry Hospital, and though it had not been long established he could see that it was by far and away the finest hospital in South Africa. So much was this the case that he was almost shocked by the money spent upon it. The wine-glasses had the Prince of Wales feathers engraved upon them in gold and everything was absolutely perfect; it was just like Guy's Hospital put down in the middle of the veldt. The inference to be drawn from this state of things was that if a private hospital could do so well why could not the hospitals of the Royal Army Medical Corps do better than they did? A great many people said that the Corps had no power of organisation. He was taken over No. 8 General Hospital by the sister superintendent. This hospital was under canvas and was situated about a mile from the town. He did not see anything very bad. The marquees were good. He found men lying in the bell tents very crowded. They looked in rather a bad state and the sister superintendent said that it was impossible to go near them; he supposed that they were attended to by the orderlies. One man asked for his medicine and they hunted up the orderly. They found the orderly and he was convinced that the man was doing his best, but the work was too much for him. There were enteric cases and dysentery cases, and the patients were lying in their clothes. They had been in their clothes for days, and some of them had not been diagnosed. Some of them had been in these tents for 48 hours and certainly they were in a pitiable condition. These men were in the bell-tents because there were no marquees for them. As soon as there were vacant marquees the worst cases were taken from the bell-tents and put into them. When they reached the marquees the men were undressed and washed and properly nursed and dieted. There were not enough nurses for the marquees, to say nothing of the bell tents. He could not speak too highly of the work of the medical men of the Royal Army Medical Corps and the nurses and the orderlies. Although there might be black sheep amongst them he never came across one, and he never came across anybody who shirked his work. He heard no complaints from the men who were in the marquees. So far as his experience and knowledge went, though the hospital was short-handed there was no absence of medical equipment or medical comforts. As for the men in the bell tents they made very bad complaints. Some of the cases were slight cases for which the bell tent was good enough, but others were serious, and no doubt there were far too many in each tent. In answer to Dr. CHURCH, the witness said that the feature of the Yeomanry Hospital was that it had fewer orderlies and more nurses than the military hospitals. Some of the men in the bell tents were semi-conscious only; some of them were very ill indeed and greatly in want of attention. In answer to the CHAIRMAN, witness said that he saw every hospital in Bloemfontein. In one case several men complained to him about their diet; they said that it was not good, and they complained that there was no fresh milk. He considered that there was cause for complaint about the milk-supply in Bloemfontein. Except for one or two cases he did not remember being without milk for his porridge in the club or hotel where he stayed. He thought that the milk of the town ought to have been requisitioned for the hospitals, which never had a sufficient supply. He felt certain that if proper steps had been taken the necessary milk for the hospitals might have been got in the town. He did not think that the convalescents were well looked after in their journeys and he gave as an instance a train he boarded on its way from Bloemfontein to Cape Town, which had 268 patients in charge of a single doctor and no orderlies. The Irish Hospital, he said, was as near perfection as could be found. The reason why these private hospitals were so much better than the military hospitals and why their death-rate was so much lower was that they had the power to refuse to take in more patients than they could look after properly. They might accept a few more patients than they were intended to accommodate, but they were never overcrowded. The patients whom they refused had of course to be sent to the military hospitals. In answer to Professor CUNNINGHAM witness said that he was of opinion that the medical officers, orderlies, and sisters connected with the Royal Army Medical Corps did everything that was possible with the resources at their command to make the patients comfortable, but he thought more might have been done by the higher authorities of the service. In the shops of Bloemfontein there was much that ought to have been bought immediately by the medical authorities. They could have had 25 or 30 mattresses turned out every day which would have been of great assistance in the hospitals and he knew that blankets were bought by private individuals and presented to the hospitals. In his opinion every blanket in the town ought to have been bought by the medical authorities. He thought that the principal medical officer ought to have looked after such a matter. He ought to have requisitioned every single thing in Bloemfontein which would be of any good to the hospitals, and he (Mr. Murray Guthrie) was perfectly certain that if he had done so he would have got a great many things. Not only so, but there were many buildings in Bloemfontein which might have been used for hospital purposes. One morning he was on the station platform about six o'clock on the look-out for some trucks which he expected. He walked along the line some distance and came across an open truck with 15 men in it. He looked at them and passed on, the sight being a common one. About 8 o'clock the truck was moved up to the platform close to his siding and he thought that the men were going to be taken out, but when he came back from breakfast about 9 o'clock or half-past 9 the truck was still there. At half-past 10 o'clock he asked the railway staff officer whether the men were going to be taken out and he said that it was none of his business and that he had no men to move them. A few men loafing about the station were picked up and the sick men were moved from the truck and ranged along the platform on the ground against the wall. They were all lying-down cases. Some of the patients were suffering from enteric fever and some of the cases were not diagnosed. Of the 15 there were eight who were stretcher cases. About 11.30 one of the men had his lips absolutely black. Witness asked one of them the history of their journey and he gave it to him. They had been upon an average about 48 hours in coming down to Bloemfontein from different places. There were eight cases which were certainly bad ones, and he gathered from the man in charge, who was not a hospital orderly, that the eight men had had among them during the 48 hours two tins of condensed milk. Witness opened one of his cases and gave the men bovril and milk. At two o'clock the men were still on the platform. Not the slightest attention had been paid to them. This was in May; not at the beginning of the campaign. He communicated with the principal medical officer, who told him that he had not been advised of the despatch of the men. He said that the civilian doctors constantly neglected to advise him of the despatch of patients, and it was not until ten minutes to 3 o'clock in the afternoon that the men were taken to one of the hospitals. This was not at all an uncommon case; it was a case that occurred almost every day. In answer to Dr. CHURCH he said that it was nobody's business to send a message to a general hospital that the men were at the station, and in answer to Mr. FREDERICK HARRISON he said that the railway staff officer had to see to the despatch of the train. He understood that since then a medical officer and an orderly had been placed at the station. In reply to the CHAIRMAN he said that when he went to Pretoria he had a conversation with Sir William Thomson, head of the Irish Hospital, who told him that things were in a bad way there, and that in the Irish Hospital they were very short of things and had 50 men lying on the ground. On June 14th he visited the seven hospitals in Pretoria and found them short of everything. He consulted the manager of the Natal Bank and asked him if he would be willing to form a committee to provide the material required, provided witness could get the sanction of the commander-in-chief. He consented and witness received the sanction of Lord Roberts. They set to work and got from the shops of Johannesburg a whole trainload of things which were distributed among the hospitals. No steps had been taken to buy anything either in Johannesburg or Pretoria by the medical authorities. The proper course of these authorities would have been to buy up everything instead of waiting for supplies to come up from Cape Town. That was what the Army Service Corps did when they entered a town, and in consequence they lacked nothing.

Mr. R. E. LAUDER, the next witness, said in course of examination that he went out in charge of the Southampton Ambulance Corps, and after being attached to No. 5 General Hospital at Greenpoint camp he acted in a stationary hospital on the Orange river. Afterwards he went with the mounted troops to Kimberley. In all his experience he saw no reasonable cause of complaint. He confessed that things were not always so desirable as one could wish or as one found them in a civil hospital, but if he were asked whether all the resources at command were utilised he would reply in the affirmative. When engaged in outpost duty near Bloemfontein he found great difficulty in getting milk for the patients.

Dr. W. M. RUSSELL, senior house surgeon at Kimberley Hospital, said that he was about two years at Kimberley and went through the siege. During the siege they had a good number of sick and wounded and they were all fairly well cared for having regard to all the circumstances. They had plenty of drugs and surgical appliances and everything else pertaining to a hospital. The only serious drawback they had was that towards the end of the siege they experienced some difficulty in getting milk. After the siege they found it necessary to open up certain buildings as temporary hospitals, the Kimberley hospital not being able to accommodate all the patients. About 40 buildings were selected as temporary hospitals, and they were filled fairly rapidly with cases of enteric fever and so-called dysentery. Of course there was a little trouble immediately after the siege, but the Red Cross Society sent up a train with supplies.

Mr. FREDERICK TREVES then gave evidence. He explained his position with General Buller and the movements of his hospital, which he described as an advanced field hospital. The hospital, he said, worked admirably. There was an immense rush of work after the battles of Colenso and Spion Kop. Some of the orderlies were indifferent, but on the whole they worked well. No doubt there were many things that stood in need of improvement. The difficulty was the difficulty of transport. For one month they were 26 miles away from a railway and such difficulties as presented themselves arose from transport. His hospital had its own transport. It was a field hospital originally equipped for 300 patients and they ultimately had to take in 800, but from Frere to Potgieter's Drift and back to Chieveley they had their own transport consisting of 260 oxen and 60 mules. They found this arrangement to work admirably and not to conflict in any way with the military arrangements. They were admirably situated in the matter of medical equipment. At times they were short of food—as, for instance, at Spearman's camp—but it was nothing unreasonable and he heard no complaints. The nursing problem was the most serious of all. He quite acknowledged that it was impracticable to have female nurses in a field hospital. He had his own two nurses with him, but that was possible because he had special provision for them. At a stationary hospital female nurses would be of the greatest possible service. There could be no doubt that they were short of utensils, this being due in their case to an oversight—they were lamentably short in this respect. He could say most emphatically that he never came across a serious case of neglect of the sick or wounded. In his opinion the wounded or sick soldier preferred the ox wagon to the ambulance and for this reason that the former was made for the country and ran smoothly. He went over all the hospitals at Pietermaritzburg and found in them no reasonable cause for complaint and he might say the same thing about Durban.

Dr. C. W. J. CHEPMELL, who acted as an Assistant Commissioner of

the Red Cross Society in Natal, gave evidence to the effect that the military hospitals in that colony offered no reasonable ground for complaint.

Nursing Sister BARWELL said that she went with the Army Nursing Reserve to South Africa, reaching Bloemfontein on March 24th. On April 2nd a considerable number of wounded were brought from Sanna's Post to Gray's Hospital where she was employed and new rooms had to be opened for their accommodation. For several days it was impossible to provide these rooms with beds and the patients were placed upon stretchers. There were two medical men and six sisters, the patients were well looked after, and there was no ground for complaint, except, perhaps, that they were badly off for some of the minor equipments.

Dr. A. CONAN DOYLE, the last witness of the day, stated that his experience was confined to the hospitals at Bloemfontein. He arrived in the town on April 2nd and stayed three months. He was connected with the Langman Hospital, which was equipped for 100 patients but at one time received 150 patients. He was sure that the pressure on the army hospitals was many times greater than that on the Langman because the former could not refuse patients. He and his colleagues were so busy that when they got out of their own hospital they did not think of going to visit another, but so far as he knew he did not believe that anybody could be charged with neglecting the sick and wounded. There were some defects but they were due to the wishes of the medical staff being overruled for political considerations. In other words, he held that there should have been less consideration for the Free Staters and more for the sick and wounded.

The Commission then adjourned.

TUESDAY, JULY 31ST.

The Commission met again to-day, when there was a full attendance of members, Lord Justice ROMER presiding.

Mr. W. BURDETT-COUTTS, M.P. for Westminster, presented himself for examination.

The CHAIRMAN explained to him that he and his brother Commissioners had read the articles in the *Times* and the speeches of the hon. Member in the House of Commons, and therefore it would not be necessary to go over familiar ground again.

Mr. BURDETT-COUTTS, in answer to questions by the CHAIRMAN, said that until he went to Bloemfontein he saw nothing to complain of in respect of the hospitals which he visited except in the case of the Woodstock Hospital. With regard to this hospital he complained of the site being badly chosen. Indeed, Surgeon-General Wilson himself told him that he was altogether dissatisfied with this hospital, that he did not think the building or the condition of it suitable for a hospital, that they had had to take it, that it was not, so to speak, a hospital of their creation; and witness, believing it to be a temporary expedient, abstained from mentioning the hospital in his letters. When he got back to Cape Town he found that the hospital had been improved and enlarged, and what he complained of was that it was not a proper place to take as the nucleus of a large general hospital. He arrived at Bloemfontein on April 7th and on May 1st he left for Kroonstad, returning to Bloemfontein about May 19th. Dealing with the state of things at Bloemfontein Mr. Burdett-Coutts said that the field hospitals reached that place in a more or less mutilated state. The field hospital described in his article was visited by him first on April 9th and he found it in a very bad condition. He did not think it right to describe it in his article because he considered it as more or less the outcome of the forced march. It was not until the railway had been running freely for nearly a month that he considered it fair to criticise the medical arrangements. With regard to No. 9 General Hospital, its tents and nothing else arrived at Bloemfontein on April 8th. These tents provided accommodation for about 800 patients. It was not until a fortnight later that the equipment for the tents came up and it was possible to put patients into them. His criticism had been, and was, that it would have been better to have sent up the tents and equipment for 400 patients in the first instance instead of sending up tents for 800 patients which were quite useless without equipment. In his letter which appeared in the *Times* on June 27th there was a phrase about "growing scenes of neglect and inhumanity." These words had been taken hold of and used in a sense which he had never intended. When he spoke of inhumanity he meant inhumanity which would arise from medical deficiencies. He had not the slightest intention of making any reflection upon the *personnel* of the Royal Army Medical Corps. He considered that their work had been magnificent and that they had performed their work in tremendous difficulties—difficulties which they ought never to have had to encounter. Examined next as to the state of the field hospital mentioned in this letter Mr. Burdett-Coutts said that the equipment in many respects might easily have been improved. All that was wanted for a mattress was a bag and something soft to put into it and if there had been the necessary initiative and energy in regard to such things he thought that beds might have been extemporised in a very few days for a large number of the patients. It was, of course, no hardship for a healthy man to lie on the ground but an enteric fever patient, aching and suffering, must have felt the ground very hard. Moreover, he had always understood that it was well to have a sick person raised off the ground. Many enteric fever patients passed the whole period of their illness in the field hospital. Serious cases could not be sent down to the town hospitals for the simple reason that the latter were crowded.

The CHAIRMAN: You say that there was want of initiative. Who was to blame for that?

Mr. BURDETT-COUTTS: I have endeavoured always to avoid putting blame upon individuals. In further examination witness said that in going through the bell tents he saw a man who the doctor told him was dying and witness could see that he was dying. He saw men lying in the mud. There had been torrential rain and it had got over the trenches and into the tents.

By Sir DAVID RICHMOND: He saw a large portion of the Russo-Turkish war and he was bound to say that he saw very much the same things at the front in Turkey as he saw in South Africa. Most of the statements he had received had been accompanied by a request that the name of the informant should not be given. In a few instances he had written to his correspondent and pointed out the protection and precautions referred to by the Chairman of this Commission in opening the proceedings, leaving it to him to decide whether or not he should tender evidence to the Commission. The statements which he had received came from various classes of people all of whom appeared to be convinced that it would injure their present or their future if they came forward with evidence.

The CHAIRMAN: There would be no injury. We should protect them amply and fully and we should be able to give them the necessary assurance.

Mr. BURDETT-COUTTS: How would you protect an officer, for instance, who considered that his future would be injured?

The CHAIRMAN: By not giving his name and not allowing his evidence to appear.

Mr. BURDETT-COUTTS: Will the evidence be seen by anybody?

The CHAIRMAN: Only by ourselves, and the evidence can be taken in such a way that nobody shall know that he has been examined.

Mr. BURDETT-COUTTS, proceeding with his evidence, gave figures to substantiate his statement in the *Times* letter that there were 20,000 sick and wounded in South Africa at the time of writing. No. 9 General Hospital he visited three times or more. He was struck by the absence of classification. The conditions of crowding were not so bad as in the field hospital to which he had referred, but a great many patients were together in what he considered a very unhealthy spot. The level of the hospital was low and a great remount compound was close to it and drained into it. When he arrived at Kroonstad he found the field hospitals with a great many sick in them. Four days after his arrival a large hotel was commandeered and made into a hospital, and this proving insufficient a Dutch church was also commandeered, and the staff of the field hospital of one of the brigades was taken to run these two hospitals. It consisted of three medical officers and six nursing orderlies in the hotel and four untrained orderlies in the church and among them they had to look after 300 patients. There were no medical comforts in these places and no beds, and none of the ordinary equipments of a hospital. A certain number of beds and mattresses were two days afterwards got hold of. He saw sick and wounded brought into the church and placed upon the stone floor in their uniforms with possibly a blanket underneath them. When these 300 patients were in the church and the hotel they had only two medical men to attend them, for the third medical man had his time taken up in trying to get things and to organise the place. What he felt about the matter was that they might have taken up on the march sufficient medical officers and orderlies and a light equipment which would have obviated the first 10 days of difficulty and pressure at Kroonstad. Before leaving Bloemfontein he bought a wagon and four mules. At the time there were four other wagons at Bloemfontein of which he had the choice, and the man who sold the mules to him said that he had 70 altogether. If the medical authorities had secured this means of transport they might have taken up medical men, orderlies, and light medical equipment. He himself had fresh milk at Kroonstad, but when he asked one of the practitioners whether he had any at the hospital he simply laughed at him. Witness wrote to the military secretary of Lord Roberts on the subject, calling his attention to the fact that the hospital had no fresh milk. In reply he received a letter stating that Lord Roberts, in company with his principal medical officer, had visited the hospital on the same day as witness, and that the principal medical officer had told Lord Roberts that the hospital was getting a large and increasing supply of fresh milk. One of the great difficulties of the situation was that the medical officers were not sufficiently resolute in asking for what they required for their hospitals. With regard to Woodstock he could present a witness who would say that operations were performed on the tables on which food was served, and that the utensils used for operations were also used for the feeding of the patients and that blood had been found on the edge of them. He could give the name of a witness who would say that at the convalescent camp at Greenpoint there were several dangerous cases of enteric fever and that the rations consisted of hard biscuit and bully beef. On the general question he thought that there was a great want of elasticity about the Army Medical Department. There were no reserves at home. He admitted that they could not maintain in time of peace the medical service required in time of war; but that made it all the more necessary to have a system capable of expansion when the necessity arose. There was, he believed, an objection in the department to female nurses and to the civil element altogether. If the system had been sufficiently elastic the three general hospitals at Cape Town could have been turned into civil institutions, and the military staffs set free to go to the front, which was their proper place. During the last 50 years the conditions of everybody had been enormously improved except those of the British soldier during a great war. His lot had not improved, and he himself did not know what medical treatment was, what it might be, and what it ought to be. If the British soldier were to be put on a gridiron and roasted, and to be told that that was the way to kill the germ of enteric fever, witness supposed that he would submit to the treatment, because the British soldier was brave and thought that bravery consisted of standing any hardships in sickness as in fighting. The opinion of witness was that they had no right to trade upon this ignorance and this bravery.

Private HAROLD MEADMORE of the Royal Horse Artillery gave evidence as to his experiences in various hospitals at Bloemfontein and Cape Town.

Sir WILLIAM MAC CORMAC, President of the Royal College of Surgeons of England, who was the next witness, gave to the Commission an account of the journeys that he made in the Cape Colony and Natal and the hospitals of one kind and another that he visited. The impression he received from seeing all these places was, he said, that the arrangements in general were simply admirable, and, he thought, would compare—and he spoke not without considerable experience—favourably with the arrangements of any previous campaign conducted by any nation in any part of the world. At Colenso, where he had the opportunity of seeing the three hospitals working in the field, there was, of course, very great pressure, but the pressure was absolutely inevitable, for it was impossible to provide for the cases that came in during and after such an engagement. In his opinion the pressure was met as well as it possibly could be met. Each field hospital had two operating-tables and these tables were in use continuously. The way in which the wounded were removed from the field on one occasion deserved, he thought, special notice; it was remarkable for promptitude. The whole of the wounded on the field of Colenso had been removed by about 3 o'clock in the afternoon of the day of the battle. He did not think that such a thing had ever happened before in war. The provision made for this was distinguished by remarkable foresight. The principal medical officer, Colonel T. G. Gallwey, with the knowledge that previous experience had given him, devised a plan whereby the services of some 1200 stretcher-bearers were obtained from among the refugees in Durban. Some of these bearers were perhaps not the most eligible members of society, but all these men worked exceedingly well and exposed themselves to all manner of risks and dangers. Some of them

were killed, many were wounded, and they worked for a wage of 5s. per day. They brought the wounded off the field by means of stretchers and brought them with the minimum of suffering. The less severely wounded were removed by ambulance wagons, which meant a terrible experience in a country where there were no roads but many stones. The hand carriage devised upon this occasion was the ideal mode of transport, especially in such a country. He should like to emphasise very strongly the fac that the principal medical officer in Natal availed himself of the opportunity which offered and organised, under the authority of General Buller, this ideal mode of transport which proved the greatest solace and comfort and saving of life to the wounded men. Another feature of the battle of Colenso was the hospital train, which was brought on to the field of battle and was under fire. This train was filled with wounded who were brought down to one of the stations on the line. Another thing was that in spite of the stress the operations in these field hospitals were conducted with every care, with the assistance of every modern appliance, and with the same precautions as those which were adopted at home, and really he thought credit and praise of no unstinted kind should devolve upon those men who did this work on the battle-field of Colenso. The wounded men came to the field hospitals ticketed with their names and numbers and the nature of their injury, which was of immense value to the surgeons. The result of the rapid evacuation of the field hospitals was that two days after the engagement all the men had been sent down to the stationary hospitals and the base hospitals or to the ships at Durban. This was a great contrast to his experience at Sedan, where there were men who lay upon the field of battle for three, and some for four, days before they received succour of any kind. He thought that there could be no doubt in the minds of those who watched the proceedings at the front that in a very trying emergency the medical officers met the duties imposed upon them in circumstances of extreme tension with a very complete success, and he knew from conversations with officers and men afterwards that they had the greatest confidence in the medical officers and realised that everything that could possibly be done for them had been done. As to the complaint about the prevalence of vermin he defied any person to prevent vermin in wooden buildings where soldiers were congregated. The only way to stop the vermin was the Chinaman's method of roasting pork—namely, to burn down the buildings. In the hospital bed he occupied at Sedan he had to endure not only bugs but also lice, and he had the same experience in the Russo-Turkish war. As to sanitary precautions in the camps, they had to remember that there were dust-storms and that the soldiers had to breathe the dust with which was mixed the excreta of the camp, and that caused a good deal of sickness. Everywhere the water was bad, and he did not think that any sanitary precautions could prevent a thirsty soldier after a long march from drinking the first water that came in his way. He was with the great march of Lord Roberts and no doubt the equipment was seriously reduced, but they had a mobile enemy to deal with and to catch him they had to be equally mobile. War was a cruel thing and the incidents of war were cruel, but the object of war was not the care of the sick and wounded—it was the winning of battles. Witness then quoted from his letters to THE LANCET and said he had nothing in these letters to withdraw or modify. He held to the opinions expressed in them in spite of subsequent criticisms by people who did not appear to know very much about war and its conditions. He thought that the medical conduct of this campaign, subject to the existing drawbacks which were inevitable, had been exceedingly good. He was sure that it would compare most favourably with the medical conduct of any previous campaign. In answer to Sir DAVID RICHMOND the witness said that there was no comparison between the medical provision in this campaign with that in the Franco-German war, so much superior was the former. The train in which he went down from the front in Natal was equipped with everything that was wanted. He saw no evidence whatever of friction between the officers of the Royal Army Medical Corps and the civil surgeons. In the Mooi River General Hospital there were a large number of comparatively young civil surgeons, and they and the army medical men were simply a happy family, free from the slightest trace of friction.

Captain ADAM, who accompanied the Indian contingent and was wounded near Dundee in October, gave evidence as to the state of things in the hospital on the neutral ground at Ladysmith, saying that there was not the slightest cause for complaint.

Lieutenant OSBORNE, one of the Australian volunteers, who afterwards joined the 16th Lancers, said that there was no cause for complaint about the Langman Hospital at Bloemfontein.

Lady CHAMPION DE CRESPIGNY stated that there were deficiencies in the hospitals at Kimberley. Men, she said, were kept lying on the ground outside and did not receive the comforts essential to their proper treatment. At Bloemfontein there was a boy who wanted wine and was told that he must buy it. In the train in which she travelled to Cape Town there were five wounded officers and 25 wounded men with no one to attend them. They had no food beyond what she gave them. Her opinion was that the medical officers should be given more power to get the things required by the patients under their charge.

Major BRIDGES of the Australian artillery said that he could not praise too highly the kindness and attention he received at the hands of the medical men and orderlies at Bloemfontein; he could not have been better treated in London. The only cause of complaint he had was that they gave him too much champagne.

The Commission then adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BERRY, R. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for Southport, Queensland.

BLACKBURN, E. W., M.B., B.Ch. Oxon., D.P.H., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Barnsley Beckett Hospital, vice J. Blackburn.

BLACKBURN, J., M.R.C.S., has been appointed Honorary Consulting Surgeon to the Barnsley Beckett Hospital.

BLAKE, STUART RYALL, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the No. 4 Sanitary District of the West Ham Union.

Births, Marriages, and Deaths.

BIRTHS.

COPEMAN.—On July 29th, 1900, at Wakehurst Place, Sussex, the wife of Sydney Monckton Copeman, M.D., F.R.C.P., of a son.

EWBANK.—On July 28th, at 13, Rockstone-place, Southampton, the wife of Arthur George Ewbank, of a son.

HOSFORD.—On July 24th, at St. John's-road, Upper Holloway N., the wife of B. Hosford, M.A., M.D., of a son.

SEARS.—On July 25th, at Lee-terrace, Blackheath, the wife of Alfred Ernest Sears, M.R.C.S., L.R.C.P., of a son.

MARRIAGES.

HALL—GEDDES.—On July 25th, at St. John's Church, Ryde, Isle of Wight, Edmund Stokes Hall, M.B. Lond., M.R.C.S., L.R.C.P., second son of John Selby Hall, of Stoneleigh, Ryde, to Jessie Alexandra, only daughter of Robert Geddes, of Trotton, St. John's-park, Ryde, Isle of Wight.

MADDEN—COX.—On July 25th, at All Saints', Margaret-street, London, W., Frank Cole Madden, M.B., B.S. Melb., F.R.C.S., of Cairo, to Madeline Alice, second daughter of William Cox, M.R.C.S., Winchcombe, Gloucestershire.

PARSONS—PARKER.—On July 28th, at Holy Trinity Church, Llandudno Frederick Gymer Parsons, F.R.C.S., son of Thos. Parsons, of Lee Kent, to May, elder daughter of Henry R. Parker, LL.D., of Syweil House, Llandudno.

DEATH.

STEELE.—On July 25th, at Byford House, York-road, Southend-on-Sea, Ernest A. T. Steele, M.R.C.S., L.R.C.P., Surgeon to St. Mary's Hospital for Children, Plaistow, E., aged 34 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

ZYMOTIC DIARRHŒA.

MR. WILLIAM BERRY, medical officer of health of the borough of Wigan, has circulated the following letter among the medical men practising in the district of which he has sanitary charge, his object being to obtain an accurate account of the deaths from summer diarrhœa:—

"MY DEAR SIR,—As the period for summer diarrhœa is at hand I venture with some degree of diffidence to call your attention to the alteration in the mode of certification in this disease, as recommended by a Committee of the Royal College of Physicians.

"Diarrhœa is a symptom of some other disease; it occurs in intestinal cancer, tuberculosis of intestines or lungs, diseases of the liver and pancreas, &c., &c., and in such cases the primary cause should be stated in the death certificate so as to prevent the death being registered as one from diarrhœa.

"From a public health point of view the deaths that should be registered as caused by diarrhœa are those which are preventable and which arise suddenly, as a rule, at this time of the year and the two following months—namely, August and September. For these the Committee of the College of Physicians recommend one of the following terms as the best designation: (1) epidemic enteritis, (2) zymotic enteritis, or (3) epidemic diarrhœa, all other synonyms to be entirely discarded.

"The synonyms in previous use were: simple cholera, cholera nostras, cholera infantum, choleraic diarrhœa, dysenteric diarrhœa.

"As our infantile mortality is high I am anxious to have as correct a certification as we can possibly get. Therefore I shall feel obliged if you will, in accordance with the recommendation of the Committee, use the term of 'zymotic enteritis' in all cases where there is no other pathological indication as to the cause of death. In other cases where diarrhœa has been a secondary symptom the primary cause should be certified and the term 'diarrhœa' may be omitted as being only a symptom.

"With every apology, I remain, yours very faithfully,

"WM. BERRY, Medical Officer of Health.

"July 18th, 1900."

"GOLDEN SYRUP."

A CASE said to be of some interest to shopkeepers and certainly of much interest to their customers was brought before the magistrates at Hyde on July 19th. A grocer was charged with selling adulterated syrup. The inspector under the Food and Drugs Act asked for one and a half pounds of golden syrup, for which he paid threepence and sent a portion to the public analyst who reported that it contained 55 per cent. of glucose syrup which is made from starch, while golden syrup, which people seem to look on as a refined treacle, is made from sugar-cane. For the defendant it was stated that he had never before been asked for "golden syrup," that his customers asked for "syrup treacle," and that most likely the inspector could not purchase it in Hyde. On the other hand, the inspector said that he bought three samples in Hyde on the same day, two of which were pure. Although this adulteration cannot be considered to be one of those which endanger health it ought not to take place, but the magistrates—perhaps because they have given up the use of golden syrup—though they fined the grocer five shillings, did not apparently think it very serious as they "believed that a *technical* offence had been committed." If people wish to have glucose it should be sold as such and not as a product of the sugar-cane.

THE "HAGEY" SYSTEM.

To the Editors of THE LANCET.

SIRS,—It may be interesting to you to know that what is called the 'Hagey" system for the cure of intemperance is about to be established in London. The Hagey Institute has been in existence for some years past in Glasgow and quite recently a similar institute has been set up in Wales. From an interview which I had with the local manager it appears that the treatment consists in the administration of some tonic and the hypodermic injection of some drug at regular intervals during the day. It is said that if during treatment the patients take any alcohol they become sick. My attention was called to the matter because the managers before they commence treatment get some medical man to certify that the patients are free from both heart and kidney disease. In this district I called the attention of the medical man in question to the rather serious risk he was running in associating himself with an institute where unqualified men undertook medical treatment. It appears that a very large sum of money has been expended in purchasing the rights to use this treatment in this country. Needless to add that it originated in America. It would be worth while to call attention to the question in order that qualified medical men might be warned of the danger of accepting office.

I am, Sirs, yours faithfully,

Cardiff, July 20th, 1900. T. GARRETT HORDER.

A QUEEN'S CHOCOLATE BOX FOR SALE.

To the Editors of THE LANCET.

SIRS,—I trust that you will pardon me for troubling you with this. I am the widow of the late ——, who resided for many years in ——. I am in very bad health and very straitened circumstances, and my eldest son, a private in the Royal Army Medical Corps, who has been out in South Africa ever since the war began, has sent me the Queen's Chocolate Box to dispose of for my benefit; and knowing from experience how very good and kind you are in rendering assistance to anyone connected with the medical profession and who may require the same, I have ventured to take the liberty to write to ask if you can and will be so very good as to assist me to find a customer for the box through the medium of THE LANCET. My health is so bad that at times it renders me quite helpless, and if I can sell the box it might enable me to undergo a course of treatment from which I have been told by the medical man who has attended me for some time I may derive a lot of benefit. I shall be grateful for any assistance you can give me in disposing of the box.

I am, Sirs, yours very truly,

A MEDICAL MAN'S WIDOW.

*** If any of our readers care to make offers for the Queen's Chocolate Box we shall be pleased to forward their letters to the writer of the above.—ED. L.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—My medical man has advised me to ask you if you can recommend me a school or home for a son of mine whom he describes as feeble-minded. His age is 11 years. He has been attending an ordinary school for some time and I have also tried myself to teach him, but he can learn nothing. You might possibly get him to say his alphabet one day but the next day it is all forgotten. I do not think his case is altogether hopeless because he can remember plenty of things that occurred a year or two ago. I may mention that my means are limited. I cannot afford much for him.

I am, Sirs, yours faithfully,

July 21st, 1900. A PARENT.

CLUB PRACTICE.

To the Editors of THE LANCET.

SIRS,—I should be glad if your columns could be opened to a defence of the club system by those who advocate or practise it—often old-established men of good standing—as contrasted with the general contumely poured upon the head of a man who does a low-fee cash practice of say a shilling. Naturally it may be comforting for a collector to bring periodically a more or less fluctuating sum wherewith to meet current expenses when bills are paid with much delay but as compared with work done it is out of all proportion. First of all, assuming that the average club subscription is five shillings per annum, which, as a matter of fact, is far above the average, while in many places children are accepted at the starvation price of one half-penny per week. This means that two visits per year exhausts, at the ordinary lowest scale of charging, that individual's premium for the whole of that said year, and in the case of a child, one visit in the same time on the above scale shows a balance on the wrong side. Moreover, children are always trespassing on the practitioner's time through their special ailments, not to mention maternal neglect. Of course, the theory is that the sound members pay for the sick ones, but in practice, as judged by work done, this is entirely erroneous. Even under the happiest conditions I have calculated that, taking 12 consecutive months, for every £1 taken at least £3 worth of work has been done in visits alone, as no record was kept of surgery consultations. As a matter of fact, on a certain Feb. 23th visits had been paid to the extent of the whole year's contract receipts, thus leaving every patient after that date to be seen and every bottle of medicine to be dispensed gratuitously. Further, apart from the above practical experience, on what grounds can the system possibly be defended, except as a charity, which I do not think certain undercutting medical men would advance, when statistics quoted in Whitelegge's Hygiene state that between the ages of 15 and 65 years the average sickness to be expected is 1·31 weeks per year, and this of course does not include children's ailments?

Then, again, a practice being as shown above trebled in work done must needs require more horseflesh and probably an assistant; consequently the net income is far below the actual turnover and the principal would be far better off with a much smaller purely private practice. Further, nightwork is materially increased, as a club patient scruples not to send at all hours for trivial reasons when a wholesome fear of an increased fee would deter any but a really important case sending; and when was a club patient grateful?

So the question may be summed up as follows. Increased work and impaired health thereby, net returns small, and, above all, the constant irritation of feeling that the profession is being sweated.

I am, Sirs, yours faithfully,

July 30th, 1900. M.R.C.S., L.R.C.P.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1900, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1900 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied, Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received: *Invention (London), Morning Leader, Ceylon Independent, Glasgow Herald, Bradford Observer, Hereford Times, South Wales News, Daily Express (London), Architect, Builder, Citizen, Scotsman, Times of India, Pioneer Mail, Yorkshire Post, Bristol Mercury, Cheltenham Examiner, Liverpool Daily Post, Western Mercury, Leeds Mercury, Golden Penny, Sanitary Record, Local Government Chronicle, City Press, Reading Mercury, Mining Journal, Surveyor, Kentish Observer, Vectis, Educational Review, Journal of Gas Lighting, Midland Evening News, Islington Gazette, Sheffield Daily Telegraph, Birmingham Daily Post, Dundee Courier, Surrey Advertiser, Local Government Journal, Chatham News, Australasian Medical Gazette, East Anglian Daily Times, Sleaford Journal, Market Rasen Mail, North Herts Journal, Buckingham Express, Public Health Engineer, Saturday Review, Norfolk Weekly Standard, Lynn Advertiser, Hertfordshire Mercury, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Axim Mines, Limited, Lond.: Anderson's College Medical School, Glasgow: Lord Avebury, Tenby; Messrs. C. Ash and Sons, Lond.; A. J. G.: Monsieur F. Alcan, Paris; Messrs. Ayrton and Saunders, Liverpool; Dr. F. W. Andrewes, London; Mr. Frank Abbott, Lond.

B.—Mr. F. Boehm, Lond.; Messrs. Blackie and Son, Lond.; Messrs. T. B. Browne, Ltd., Lond.; Messrs. W. V. Bowater and Sons, Lond.; Messrs. Bostel and Sons, Lond.: Messrs. W. H. Bailey and Son, Lond.; Messrs. R and J. Beck, Lond.; Sir T. Lauder Brunton, Lond.; Messrs. P. B. Burgoyne and Co., Lond.; Mr. W. G. Black, Glasgow; Mr. Henry Bradford, Lond.; Bootle Borough Hospital, Secretary of.

C.—Messrs. Cassell and Co., Lond.; Mr. T. J. Croke, Harrogate; Corporation of Birmingham, Medical Superintendent of; Messrs. J. and A. Churchill, Lond.; Dr. Corfield, Lond.; Mr. P. Carmady, Trinidad; Messrs. W. and R. Chambers, Edinburgh; Dr. E. Cureton, Shrewsbury.

D.—Dorchester County Asylum, Medical Superintendent of; Durham County Asylum, Winterton, Steward of; Dover Hospital, Secretary of; Messrs. Dixon and Hunting, Lond.; Messrs. Darton, Gibbs, and Co., Oldbury; Mr. W. G. Dickinson, Lond.; Mr. E. G. Dutton, Brighton.

E.—Messrs. Evans, Lescher, and Co., Lond.; Dr. F. W. Edridge-Green, Hendon; Eye, Ear, and Throat Hospital, Shrewsbury, Secretary of: Dr. James Edmunds, Lond.; Mr. F. Edmunds, Chesterfield.

F.—Dr. H. M. Fletcher, Liverpool; Mr. H. Frowde, Lond.; Messrs. Fairchild Bros. and Foster, Lond.; Mr. C. E. S. Flemming, Bradford-on-Avon; Messrs. B. Finch and Co., Lond.; Captain P. C. Fenwick, Lond.; Mr. F. Fox, Lond.: Mr. S. T. Fairland, Lond.; Dr. Fison, Salisbury.

G.—Messrs. Giles, Schacht, and Co., Clifton; G. E. R. Co., Lond.; G. W. G.; Dr. M. H. Gordon, Lond.

H.—Mr. O. L. Holst, Eastbourne; Mr. W. Herbert, Liverpool; Dr. W. Gordon Hall, Sirmoor State, Nahan, India; H. B.; Messrs. J. S. Hamilton and Co., Brantford, Canada; Dr. Walter K. Hunter, Glasgow.

I.—Messrs. Ingram and Royle, Lond.; International Purification Syndicate, Lond.

J.—Mr. T. Johnson, Woodsetton; J. E. K., Lond.; Dr. F. de Jersey, Reading.

L.—Mr. E. W. Longden, Port Talbot; Legal, Woking.

M.—Dr. G. Murray, Newcastle-on-Tyne; Macclesfield Infirmary, Secretary of; Medical Graduates' College, Lond., Secretary of; Mr. R. B. Marston, Lond; Dr. J. S. Martin, Rotherham: Manchester Royal Ear Hospital, Secretary of; McD.

N.—Nottingham City Asylum, Medical Superintendent of: Messrs. Newton, Chambers, and Co., Thorncliffe; Messrs. Nicolay and Co., Lond.; Mr. H. Needes, Lond.; Dr. N.

O.—Oldham Infirmary, Secretary of; Messrs. Orridge and Co., Lond.

P.—Patent Fish Food Syndicate, Greenock: Mr. H. Palmer, Lond.; Mr. Y. J. Pentland, Edinburgh; Dr. Pye-Smith, Lond.; Pharmacological Institute, Frankfort, Manager of; Mr. F. Pamphilon, Gloucester.

R.—Royal Hants County Hospital, Winchester, Secretary of; Royal United Hospital, Bath, Secretary of; Messrs. Reynolds and Branson, Leeds; Messrs. Richmond and Co., Lond.; Rotherham Hospital, Secretary of; Messrs. S. Rentell and Co., Lond.; Mr. J. M. Randle, Tenterden; Mr. Mayo Robson, Leeds; R. F. McA.

S.—Messrs. W. H. Smith and Son, Manchester; Mr. D. Samuel, Gorseinon; Sir Felix Semon, Lond.; Mr. Sydney Stephenson, Lond; Sussex County Hospital, Brighton; Messrs. J. Symons and Co., Lond.; Mr. H. P. Snewin, Littlehampton.

T.—Tottenham Hospital, Secretary of; Torquay, Town Clerk of; Tallerman Institute, Lond., Secretary of; Mr. O. B. Thomas, Lond.; Dr. Hugh Thursfield, Lond.; Dr. Stopford Taylor, Liverpool.

V.—Victoria Hospital for Children, Secretary of; Vinolia Co., Lond.; Victoria Hospital, Folkestone, Secretary of.

W.—Mr. M. A. Withers, Lond.; West Bromwich District Hospital, Secretary of; Messrs. J. Wright and Co., Lond.; Rev. J. Wells, Pollokshields; Messrs. Wilson and Son, Lond.; West Ham Hospital, Secretary of.

Z.—Messrs. A. and M. Zimmermann, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. Aikman, Hillhead; Apollinaris Co., Lond; A. E. W.; Miss A. J. N., Lee; A. C.; A. L.; A. R. M.; A. M. L.

B.—Mr. A. S. Barrow, Indwe, Cape Colony: Mr. J. L. Bragg, Lond.; Mr. H. Butterfield, Northampton; Mr. S. H. Benson, Lond.; Birmingham City Asylum, Clerk of; *Birmingham Daily Post*; Mrs. E. M. Barragry, Lond.; Black wood, Newbury.

C.—Mr. E. P. Court, Hambledon; Messrs. Carnrick and Co., Lond.; Messrs. E. Cook and Co., Lond.; Corporation of Manchester, Treasurer of; C. P.: Messrs. Craven, Dunnill, and Co., Jackfield; Cornwall County Asylum, Bodmin: Miss E. B. Cuffe, Woodhall Spa; Messrs. Cuxson, Gerrard, and Co., Oldbury; Clayton House, Kennington.

D.—Mr. R. Davis, Lond.; Mr. J. T. Davenport, Lond.; Dr. J. Don, Steytlerville, Cape Colony; Mr. A. K. Dresser, South Hayling; Mr. H. De Stvrap. Shrewsbury; Messrs. Duncan, Flockhart, and Co., Edinburgh; Mr. E. C. Dean, Bridgetown, W. Australia; Dr. D.; Messrs. H. Dawson and Co., Lond.: Mr. A. J. B. Duprey, Grenada; Dr. T. S. Dowse, Lond.

E.—Dr. E. Elsmere, Barton-on-Humber; Exeter City Asylum, Clerk of; Mr. A. G. Ewbank, Southampton; E. S.

F.—Mr. F. P. Flood, Merthyr Tydvil; Dr. H. Forrester, Weybridge; Messrs. Ferris and Co., Bristol; Mr. W. A. Frost, Lond.; Mr. W. J. Furnival, Stone.

G.—Mr. S. L. Glynn, Shepton Mallet; Messrs. Gale and Sons, Birmingham: Mr. O. W. Gange, Tuxford; G. K.; G. C. S.; Grove House Asylum, Church Stretton, Secretary of; Gloucester County Asylum, Clerk of; Messrs. Guyot, Guenin, and Son, Lond.; Great Eastern Railway Co, Lond.; General Apothecaries Co., Lond.; Mr. J. J. Griffiths, Lond.; G. S.

H.—Messrs. Hogg and Son, Lond.; H. C. P.; Hendon Grove Asylum, Hendon, Licensee of; Messrs. Hastings Bros., Lond.; Messrs. Hooper and Co., Lond.; Mr. A. R. Henchley, Blagdon; Mr. W. T. Hawthorn, Wellington; H. P. G.; H. C. T.; Mr. J. J. Harding, Ballincollig.

I.—Ingham Infirmary, South Shields, Secretary of.

J.—Jenner Institute of Preventive Medicine, Lond.; Messrs. J. and H. Jones, Dolgelley; Mr. C. Jennings, Deal: J. T.; Messrs. Jewsbury and Brown, Ardwick Green; J. P. N.

K.—Dr. W. R. Kingdon, Lond.; Mr. W. V. Kane, Nagpur, India; Kent and Canterbury Hospital, Secretary of.

L.—Mr. H. K. Lewis, Lond.; Mr. G. M. Lloyd, Rock Ferry; Lunatic Asylum, Portsmouth, Medical Superintendent of; Messrs. E. and S. Livingstone, Edinburgh; Locum, Dalston.

M.—Mrs. Mason, Ulverston; Mr. W. Martindale, Lond.; Messrs. Maclehose and Sons, Glasgow; Maltine Manufacturing Co., Lond.; Dr. F. Merwanji, Troop Bazar, India; M.D., Flitwick, M. S. P. S.; M. K.; Mr. F. G. C. Martin, Lond.; Manchester Medical Agency, Secretary of; Messrs. McDougall Bros., Manchester.

N.—Northern Medical Association, Glasgow, N. C.

O.—Mr. E. Owen-Cox, Cleobury Mortimer; Mr. C. A. P. Osburne, Norwich.

P.—P. J. S.; P. P.: Practice, Manchester; Mr. R. Pattie, Birmingham.

Q.—Mr. T. Querney, Komgha, Cape Colony.

R.—Messrs. W. A. Ross and Sons, Belfast; R. D. M.; R. A.: Mr. B. Robinson, Rocester; Radcliffe Infirmary, Oxford, Secretary of; R. J.; Dr. D. T. Richards, Risca.

S.—Dr. J. A. Shaw-Mackenzie, Lond.; Mr. H. B. Snewin, Littlehampton; Mr. W. Smith, Aberdeen; St. Andrew's Hospital, Northampton, Secretary of; Dr. H. Snow, Lond.; *Sheffield Independent Press*: Miss M. E. Sutton, Collamer, U.S.A.; Dr. G. C. Simmons, Paris; Mr. H. W. Scriven, Lond.: Dr. A. Shearer, Newtown; S. H. B.; Dr. E. H. Snell, Coventry; Dr. R. Sturgis-White, Cradley; Sheffield Royal Hospital, Secretary of; Stamford Hill Dispensary, Secretary of; Messrs. Spiers and Pond, Lond.; Dr. A. Sayba, Alexandria.

T.—Dr. C. B. Taylor, Nottingham; T. H.; T. S. B.; Tiverton Infirmary, Secretary of; Messrs. J. Turner and Co., Queensferry; T. A. D.; T. N.; Mr. D. J. Thomas, Nantymoel; Mr. J. Thin, Edinburgh.

W.—Messrs. Widenmann, Broicher, and Co., Lond.; Mrs. O. Wainwright, Brentford; W. B. F.; Mr. F. F. Wellington, Lond.; Worth's Food Syndicate, Cheltenham; Mr. C. E. Whitington, Tuxford; Mr. S. Wand, Leicester; Wonford House Hospital, Exeter, Secretary of; Mr. J. F. Walker, Swallowfield, W. G. N.; W. L. R.; Dr. W. S. Whitcombe, Aldermaston; Dr. A. F. Wilson, Lond.; Wrexham Infirmary, Secretary of.

Y.—York County Hospital, Secretary of.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France,—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

Address in Obstetrics:

THE MATERNAL MORTALITY IN CHILDBED

Delivered at the Annual Meeting of the British Medical Association at Ipswich on August 3rd, 1900,

BY WILLIAM J. SMYLY, M.D. DUB., F.R.C.P. IREL.,

VICE-PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND; GYNÆCOLOGIST TO THE ADELAIDE HOSPITAL, DUBLIN.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—As the century draws to its close a retrospect is not only excusable but advisable. At such a time we naturally pause to consider the way in which we have come, how we differ from our predecessors, and what we have gained in these hundred eventful years. Periodical literature is full of such retrospects. Our modes of life, the discoveries of science, our means of locomotion, and our methods of warfare are contrasted with those of 1800, and the verdict is that in the present century a greater advance has been achieved than in all that preceded it. Medicine and surgery have shared to the full in the advances of this wonderful age, and it now falls to my lot to show how midwifery has participated in the general improvement.

In considering the history of midwifery many subjects suggest themselves which would offer ample material for an address in obstetrics. The struggle between science and nescience, as represented by medical practitioners and midwives, commenced in the sixteenth century, was fought in every civilised country with varying fortune, and continues in our own time to be a burning question. The contest between radicals and conservatives, or those who incline to operative interference and those who rely more exclusively on nature, are as fully represented amongst us here to-day as they were in the days of Levret and Smellie, of Boër and Osiander. The rise and fall of lying-in hospitals, their almost total extinction and resuscitation in our own time, have no parallel in medical history. To have closed these institutions would have been to have sealed the fountain of knowledge at its very source, yet few could deny that Simpson was actuated by the highest motives of humanity in the campaign which he carried on against them. The development of obstetrical literature, the origin and development of obstetrical and gynæcological societies, national associations, and international congresses, each and all of these would have offered ample material. I have preferred, however, a subject much more familiar and often dealt with, but at the same time of much greater importance than any other that could be chosen—namely, the maternal mortality in childbed.

THE FAILURES OF THE EARLIER PART OF THE CENTURY.

The history of midwifery is a long one, extending back to the earliest times. The Hebrew Scriptures abound in obstetrics, and midwives as a class are distinctly mentioned therein. A knowledge of the art existed amongst the Indians, the Greeks, and the Romans, and later amongst the Arabians, but scientific midwifery may be said to have commenced with Ambroise Paré in the sixteenth century. During the intervening years up to the present time it has been advanced by ardent and zealous investigators, many of whose names can never be forgotten—Mauriceau, Deventer, the Chamberlains, Levret, Baudelocque, Sir Fielding Ould, Smellie, William Hunter, Boër, Naegele, the Ramsbothams, Sir James Simpson, Matthews Duncan, Robert Barnes, and a host of others too numerous to mention. But in considering the improvement in the death-rate in childbed we need not go back many years. It did not take place gradually as the light of science slowly dawned upon our art, but occurred suddenly in the seventh decade of the present century. The observers of the past pursued their object in the face of failure little short of disaster. Their zeal and perseverance were not rewarded by success, but, on the contrary, the more famous the professor, the wider his field of observation, the greater his industry, and the more searching his investigations, the worse were his results. In the first half of the present century the mortality amongst parturient women, especially in hospitals, was probably greater than in any other period of the world's history.

THE DECLINE OF MORTALITY IN LYING-IN HOSPITALS.

Towards the close of the seventies, however, a sudden and salutary change took place. In the Paris Maternity, for example, the mortality dropped in one year from 8 per cent. to 4 per cent., and in 1881 to 1 per cent., and has since improved, and in all the hospitals of Europe a similar change occurred. As to private practice, however, I am not able to give any facts founded upon reliable statistics. Dr. Matthews Duncan in his monograph on "Mortality in Childbed" published in 1870 deliberately stated that "all attempts at ascertaining scientifically the mortality in childbed must be given up." Dr. McClintock also said about the same time, "With our great registering machinery all at work we cannot find out what is the mortality of childbed in London. For my part I think that obstetrical common sense will be well contented if the true childbed mortality of modern London is at all less than in London of 1660. It is very doubtful if it is even now as low as 1 in 107." Matthews Duncan after careful investigation agreed with McClintock that the mortality in private practice was not less than 1 in 120. His own results were 1 in 105, McClintock's results were 1 in 108, and Dr. Churchill's results were 1 in 159. In the face of such results in the hands of the best men it is idle to talk of the general mortality having been at that time 19 per 10,000. In comparing the results, therefore, of modern with ancient practice, we must confine ourselves to hospital statistics, and I have no doubt that the results in private practice are a faithful reflection, perhaps some years later, of the teaching in those institutions.

Statistics of the Rotunda Hospital.—I will take as an example for the purpose of contrast the results obtained in the Rotunda Hospital during Dr. Johnston's mastership, from 1870 to 1876, and the seven years from 1890 to 1896. I have chosen Dr. Johnston's report because it was the period immediately preceding the introduction of antiseptics and because his results were considered at the time to have been remarkably good. During the first period (from 1870 to 1876) 8092 women were delivered in the hospital, of whom 169 died, or 1 in 45·5; during the second period (from 1890 to 1896) 9085, with 50 deaths, or 1 in 181·7, showing a saving of about 200 maternal lives in every 10,000 deliveries. If we adopt the classification of the Registrar-General the deaths appear as due to:—

—	1870–1876.	1890–1896.
1. Septic infection	89·1 in 90·9	10·1 in 908·5
2. Accidents of childbirth	46·1 in 176	24·1 in 378
3. Unconnected with childbirth.	34·1 in 238	16·1 in 568

Similar results are shown by hospitals generally. It is evident, therefore, that in hospitals at least a marked improvement has taken place during the past quarter of the century in all the three groups—death from puerperal fever, accidents of labour, and other causes.

PUERPERAL FEVER OR SEPTIC INFECTION.

The greatest improvement is observable in this group, and I shall offer no apology for dwelling at length upon the way in which it has been brought about.

In the beginning of the century obstetricians were ignorant of the nature of this, the chief cause of childbed mortality, and were helpless either to prevent or to cure it. Epidemics became more frequent and more virulent; and obstetricians endeavoured by clinical observation and post-mortem examination to discover its nature; but unfortunately both these roads to knowledge were pursued by the same individuals and with disastrous results. In Paris Cruveilhier, the most illustrious of French pathologists, was appointed physician to the Maternity; he multiplied his researches and at the same time the mortality in that institution increased. Little of value was added to our knowledge by these investigations, and even in 1872 Dr. Churchill reflected the general ignorance when he published in the sixth edition of his well-known work his opinion that puerperal fever was due to mental emotion, cold, putrefaction of portions of retained placenta, gastro-enteric irritation, the state of the atmosphere, epidemic influences, and contagion. With regard to the latter he felt compelled by the evidence to admit the

possibility of its being conveyed and communicated or excited by those who had attended midwifery cases after being employed in dissection or post-mortem examination, or who were much in contact with fever patients, but in all other cases he attributed its occurrence to epidemic influence. It is pleasant to turn from this general ignorance and mark the first beams of the dawning day.

Dr. White of Manchester.—Towards the end of the last century a remarkable work on the management of pregnant and lying-in women was published by Dr. White, a surgeon practising in Manchester. In that work, published in 1791, he attributed puerperal fever to the absorption of putrid matter by the lymphatics and vessels of the womb. He arrived at this conclusion by observing the similarity, in causation and symptoms, in putrefactions occurring in other parts of the body. In chronic abscess, for example, dangerous symptoms similar to those of puerperal fever set in after it had been opened and the air had gained admission; so also in childbed, fever did not occur until after the child was born. He further observed that when a putrid wound was cleansed the symptoms abated, and that where the disease was so situated that it could be removed by amputation they entirely disappeared, and from this he concluded that absorption of putrid matter was the cause of puerperal fever. His treatment was therefore directed towards the prevention of putrefaction and the elimination of putrid matter should it have already formed. To these ends he advocated thorough ventilation, cleanliness, and drainage. Foul stagnated air, human effluvia, heat and moisture, were to be avoided. Free and even cold air should pervade the apartment, and clean linen be supplied every day. The lochia, if permitted to stagnate in the vagina, would soon become putrid, for, he said, it is well known that the mildest humours in the human body, if suffered to stagnate, become acrid as soon as the air has access to them. He therefore encouraged his patients to sit up several times a day, and even to leave their beds, so as to prevent a lodging of offending matter either in the vagina, uterus, intestines, or bladder. Perhaps the most remarkable statement in this work is the following: "I must not omit to mention," he says, "the good effects I have experienced from emollient or antiseptic injections into the uterus by means of a large ivory syringe or an elastic vegetable bottle in those cases where the lochia have become acrid or putrid, and by being absorbed into the circulation have served as a constant fomes to the disease. I have by this means known the fever much assuaged, and in many cases wholly extinguished, for though the quantity of the lochia is not to be much regarded the quality of this discharge is a matter of infinite importance." One cannot but wonder at White's independence of opinion and the general correctness of his views. He was only a provincial surgeon, yet he did not shrink from stigmatising the teaching of the obstetric world of his day "as a set of pernicious maxims and opinions, built upon ignorance and supported by prejudice and obstinacy." With truth he declared that the slightest remark drawn from real observation is of more utility than the most extensive theory of causes drawn from hypothesis alone. Ignorance, prejudice, obstinacy—these were the forces against which he combated, and, alas, in vain, nor for 50 years afterwards did another champion take the field against them—to perish in the encounter.

Ignaz Philipp Semmelweis.—That champion was Ignaz Philipp Semmelweis. With what feelings of regret and shame should we recall his name. Not long ago obstetricians in every land combined to raise a memorial to it, but during his sad life no such recognition of his virtues smoothed his thorny road. Of us it may well be said, "Your fathers killed the prophets, and ye build their sepulchres." Had they but learned of him instead of ridiculing, opposing, and neglecting him, how different would have been the history of obstetrics in the past half-century. Obstetricians would have led the van and have taught the surgeons antiseptic methods; but the contrary has been the case, and surgeons have taught us what Semmelweis strove to teach our fathers 20 years before. What an amount of human life would have thus been saved, what untold anguish and remorse might there have been avoided; but ignorance, prejudice, and obstinacy prevailed. In 1846 Semmelweis, a young man of 28, was appointed assistant to Professor Klein in the maternity department of the Vienna Hospital. Not only was his sensitive nature shocked by the fearful mortality which prevailed in the department attended by the students, but his observant mind was also struck by the more favourable results obtained in the neighbouring department reserved for the instruction of pupil midwives. Reviewing the history of the institution he found that from 1784 to 1822 the physicians connected with it performed no post-mortem examinations and that the average mortality during that period was 1·25 per cent.; from 1825 to 1833 post-mortem examinations were made and the mortality increased to 5·3 per cent. In 1839 the clinic was divided into two departments and the second was reserved for pupil midwives; the mortality in it fell at once to 2·6 per cent., whilst in the other where the students attended it increased to 9·5 per cent., and this proportion remained the same for the five succeeding years except during the years 1841 to 1843 when during an epidemic of 20 months' duration the mortality in the first department averaged 16 per cent. and at one time rose even to 31·3 per cent. At the post-mortem examination of his colleague Kollitshka who died from septic poisoning Semmelweis was so struck by the similarity between the appearances in that case and in the patients who died from puerperal fever that he concluded that the cause must be the same in both—namely, an infection from without due to the transportation of cadaveric poison by the fingers of the attendants—and he directed that before attending lying-in women they should wash their hands in a solution of chloride of lime. The mortality at once sank to 3·05 per cent. Subsequently, however, he formed the opinion that any organic substance in course of putrefaction, and especially the discharges of women with septic diseases, and even air charged with putrefactive matter, might cause fever; and from this time the hands were disinfected in every case, as well as the instruments and the materials used in cleansing the patients, and the sick were separated from the healthy. The mortality fell to 1·27 per cent. Having been defeated by the intrigues of his colleagues whose animosity he had aroused in his candidature for a professorship in Vienna, he went to Buda-Pesth, where he filled the office of senior physician to the Rochus Hospital for a period of six years, and under his administration the mortality in that institution averaged only 0·85 per cent. Having again been unsuccessful in his candidature for the professorship in Prague, he retired from practice and devoted his energies to publishing his great discovery in a work on the "Nature and Prophylaxis of Puerperal Infection." The story of Archimedes springing from his bath and rushing forth shouting "Eureka, eureka!" is a comedy in science, but the history of this man urging his great discovery upon those who received it with indifference, or hostility, and ridicule, even stopping the passers-by in the streets to impress on them the importance of life-saving truths which they would not receive—this forms a tragedy fit to make the angels weep. In these endeavours he fretted and fumed his life away, until at last reason departed and he was consigned to the lunatic asylum in Vienna, where four years later he died from septic poisoning, that very disease which he spent his life in combating. Semmelweis discovered the same truth as White had done 50 years before, that putrefaction was the cause of puerperal fever, but he added another and much more important one—namely, that the disease could be conveyed to the patient by her attendants. These two methods he termed auto- and hetero-infection.

ANTISEPTICS.

Long before Semmelweis fretted himself into insanity he might have discovered, had he had patience to observe it, that the seed which he was sowing had already taken root and would soon bear abundant fruit. Michaelis and Lange had adopted his views with success. Simpson warmly advocated them in this country and pointed out their applicability to operative surgery. The wonderful discoveries of Pasteur were published two years before his death, and these discoveries not only confirmed his views but placed them upon a firm scientific footing. Lister was already in the field in 1864 and astonished the world by the wonders of antiseptic surgery. But it was not until 1870 that antiseptic principles were applied to obstetric practice, and practically banished puerperal fever from our hospitals. Stadfeld, Bischoff, Fritsch, Schroeder, Breisky, and Lucas Championnière were the pioneers in this movement. At first Listerian methods were closely followed, but not only was the original system too cumbrous for general practice, but it was soon discovered that many of its details might with advantage be abandoned.

THE DOUCHE.

The spray was replaced by the douche, and the vagina was douched with antiseptic fluids before and after every

labour. Soon the uterus was also included in the process, and prophylactic douching reached its climax when permanent irrigation or instillation was introduced by Schücking. Soon, however, serious accidents and even deaths, the result of the douche, began to multiply. These were due to injection of air and antiseptic fluids in the veins. In some cases the uterus was perforated and poisonous fluids were injected in the peritoneal cavity, but, worst of all, the douche proved to be a cause of the very disease which it was intended to prevent. Runge described an epidemic in the Charité Hospital, Berlin, in which the mortality remained at 3·8 per cent. so long as prophylactic douching was employed, but immediately sank to 0·39 per cent. upon its abandonment. Breisky reported a similar experience. In a series of papers in the *Archiv für Gynäkologie* Professor Leopold clearly showed that by thoroughly disinfecting the external parts and avoiding unnecessary examinations far better results were obtainable than by prophylactic douching. In 1888, however, in consequence of the results of bacteriological examination of vaginal discharges he returned to vaginal douching: immediately the morbidity increased by 3 per cent. The next year he again gave up the irrigator, and this was followed by an improvement of 9 per cent. I need hardly explain that by morbidity is meant a rise of temperature even once to 100·4° F. The whole question of the value of prophylactic douching—and it can hardly be said to have been finally settled even yet, for many leading obstetricians both in this country and abroad still resort to it—resolves itself into the probability or even possibility of auto-infection. That the vaginal discharge often contains germs many of which are apparently septic or saprophytic is undeniable, but are these germs really dangerous to the patient, and can they be removed by antiseptic measures? These are the two important questions. In 1888, Winter examined the discharge in 20 women, and found 27 varieties of micro-organisms. In 50 per cent. of these women he found streptococci and various saprophytes, though in an attenuated condition. In 1890 Streffeck made a similar series of examinations, and found pathological organisms in nearly the same proportion of cases. He therefore advocated vaginal douching. Döderlein's investigations in the same direction led him to classify discharges as normal and pathological. The normal were of a creamy consistence, intensely acid in reaction, and contained usually a pure culture of an organism which he named the vaginal bacillus and to which he attributed the acidity of the discharge. The pathological discharge was of thinner consistence, often puriform in appearance, it was feebly acid, neutral, or even alkaline in reaction, and it contained a great variety of micro-organisms, some of which were dangerous. The normal discharge he discovered to be not only innocuous but actually antiseptic. From experiments he concluded that where the discharge was normal vaginal douching was unnecessary, but, on the contrary, where it was pathological a thorough disinfection of the canal was imperative. Döderlein's investigations were repeated in the same clinic in Leipsic by Krönig. In 56·8 per cent. he found the discharge to be normal and in 43 2 to be pathological, but in none of these was it either neutral or alkaline in reaction. He agreed with Döderlein as to the antiseptic properties of the normal discharge, but denied that it was due to the vaginal bacillus, and found, on the contrary, that the so-called pathological discharges which, did not contain the bacillus also possessed a similar bactericidal property. He injected cultures of the bacillus pyocyaneus, staphylococcus aureus, and even streptococcus pyogenes into the vagina and found that they were all eliminated within 24 hours. A most important observation with regard to douching was that in cases in which, after injecting the micro-organisms, he at once thoroughly scrubbed out the vagina with a 1 per cent. solution of corrosive sublimate or lysol, they had not entirely disappeared at the end of 36 hours. The douche, therefore, not only failed to dislodge them, but so altered or removed the natural discharges that for at least 12 hours the normal bactericidal action of the vagina was annihilated. The result of these investigations was that vaginal prophylactic douching was altogether abolished in the Leipsic Hospital, with the result that morbidity was thereby reduced 10 per cent.; the gravity also of the infected cases was less, so that the number of women who were detained in the hospital beyond the tenth day was reduced by one-half. Some of the most distinguished French accoucheurs whilst admitting the importance of the facts I have mentioned still adhere to the prophylactic douche and with good results, but at the same time they point out the absolute necessity for observing perfect asepsis; the external parts of the patient, the hands of the operator, the instruments, and even the water must be absolutely pure. When we remember, however, that this operation, if carried out two or three times every day, must necessarily be entrusted to a nurse I have no hesitation in saying that the preservation of perfect asepsis or anything approaching it will be found in general practice to be absolutely impossible. Where are such nurses to be found? In these countries they are certainly rare and from personal experience I feel certain that routine douching has been productive of much more harm than good.

THE HANDS OF THE ATTENDANT.

We now come to the attendant and our attention may be concentrated upon his hands. The teaching of Semmelweis and Sir James Simpson that infection is carried chiefly by the hands of attendants is now the generally accepted opinion. If I were to state that where there had been no handling there would be no septic infection I should not be very far from the truth. Leopold has clearly proved that patients who deliver themselves without any vaginal interference make better convalescences than those who have been examined even with the most scrupulous antiseptic precautions. Experience therefore proves—what bacteriological investigation would lead us to expect—that an absolutely aseptic condition of the hands cannot be ensured by any known process, and from this we learn: (1) to avoid as far as possible septic contamination; (2) to spare no pains to render our hands as innocuous as possible; and (3) to restrict local interference within the narrowest bounds. The last of these includes not only unnecessary operative interference but also needless vaginal examinations. We can limit the numbers of such examinations best by substituting for them external manipulations; and next to antiseptics I consider this to be the most important advance in modern midwifery. By whom it was introduced, or when, I know not, but its systematisation and popularity we owe to Pinard, Credé, and Leopold. In 1888 Credé wrote as follows: "Even the simplest manipulation may cause infection. It should therefore be laid down and taught as a fundamental principle that internal examination of parturient women should be altogether avoided or restricted within the narrowest possible limits; it can be very well replaced by external examination. To instruct their pupils as thoroughly as possible in this method is the present and future duty of teaching institutions."

DIAGNOSIS BY EXTERNAL EXAMINATION.

By external examination we can tell whether the woman is pregnant or not, and the period to which the pregnancy has advanced, and we can ascertain the presentation and position of the fœtus, whether it be living, dying, or dead, and whether there be one child or more in the uterus. We can also tell whether the patient is actually in labour or not, and the course and progress of the labour may be followed with accuracy. Pelvic deformity is suggested by pendulous abdomen, abnormal mobility and obliquity of the uterus, especially in primiparæ, and in the latter also, excepting hydramnios, hydrocephalic fœtus and plurality of children, all of which may be diagnosed by this method. It is an ominous sign, where labour has actually commenced, to find the head still above the brim; the way in which it enters the cavity is also characteristic. In prolonged labours danger to the mother is indicated by thickening of the upper and thinning of the lower uterine segments; the elevation of the contraction ring and the prominence of one or both round ligaments. External examination is equally useful in the third stage of labour, and its proper conduction depends upon it. The external examination then is the one chiefly to be relied upon, not only because it is safer, but also because it gives more information to the examiner, and because it is easier and more reliable. Having for many years practised the vaginal examination exclusively, I found it difficult to persuade myself of the truth of the latter assertion; but not only has my own individual experience proved to me that this is so, but in the Rotunda Hospital, where the students are obliged to write down upon the bedcards the result of each examination, I found that mistakes in diagnosis were much more frequent with the vaginal than with the abdominal method. There are two things, however, which can only be made out by vaginal examination, and these are the condition of the os uteri and a prolapse of the umbilical cord; and if for any reason, such as inexperience on the part of the

examiner or insuperable difficulties, such as very fat or rigid abdomen on the part of the patient, the results of the abdominal examination are unsatisfactory, a vaginal examination becomes necessary.

DIAGNOSIS BY INTERNAL EXAMINATION.

But before each internal examination the practitioner should remember that it is an operation never altogether devoid of risk and he should be fully persuaded in his own mind as to its necessity. For my own part I seldom examine internally more than once in the course of a natural labour, and I endeavour to do so as soon as possible after the full dilatation of the os, as indicated by the rupture of the membranes or a change in the character of the labour pains. I need not delay to describe the disinfection of the hands. Many excellent methods are in vogue, but thoroughness in carrying it out is of more importance than the selection of any particular method; at the same time in general practice it should be simple as well as efficient.

TREATMENT.

In the treatment of the disease when once established we have also made considerable advances. Local disinfection by antiseptic douching is generally employed, and the curette, abdominal section, and ablation of the infected organs have been employed with success, but are hardly in a position for a dogmatic pronouncement upon their value in an address which is not to be followed by discussion. For the same reason I shall not speak of the antistreptococcic serum, but the general treatment with which I have met most success, and which is, I believe, now most generally adopted, is that introduced by Runge in 1886, and consists in cool bathing, nourishing diet, avoidance of internal antipyretics, and free administration of alcohol.

CONCLUSION.

The subject with which I have dealt is, no doubt, lacking in novelty, and the method an elaboration of the old saying that "meddlesome midwifery is bad," but I have been urged to its consideration by the opinions expressed by Hegar, Boxall, and Cullingworth, that in private practice there has as yet been no improvement. If this be true, or even partially true, it proves that those who undertake the care of parturient women are not yet alive to the responsibilities of their calling, and I have no doubt that a faithful adherence to the principles the development of which I have briefly sketched will result in a vast saving of most valuable lives and will prevent you individually from standing—as many of us have done in the past—helpless spectators of a fatal malady which an accusing conscience whispers might have been averted.

Introductory Remarks
ON
THE PREVENTION OF INSANITY.

Delivered at the opening of the Section of Psychology at the Annual Meeting of the British Medical Association at Ipswich on August 1st, 1900,

BY R. PERCY SMITH, M.D., F.R.C.P. LOND.,
LECTURER ON PSYCHOLOGICAL MEDICINE AT CHARING-CROSS HOSPITAL; PRESIDENT OF THE SECTION.

GENTLEMEN,—Probably few circumstances connected with insanity have stirred the public mind more in the last few years than its real or apparent increase. The question is constantly asked by people, Is it not very much on the increase? and it seems to me to be worthy of consideration by this section of the Association whether we as medical men concerned in the treatment of mental disorders are doing all we can to check what at any rate is a most serious increase in the actual numbers of the insane. As the public owes the checking of the ravages of small-pox, the notification of infectious diseases, the improved sanitary measures which have led to such a marked diminution of the death-rate, and now in all probability the successful coping with the large amount of illness due to malarial poison—to name only a very few instances—to the medical profession, so undoubtedly it will be to that profession that the public will look for guidance in what is assuredly a very serious question for the future of our population. The annual report of the Commissioners in Lunacy for the year 1898 (published in June, 1899), begins with the remark that the total number of patients under their cognisance in England and Wales on Jan. 1st, 1899, was 105,086, "being an increase on the corresponding number on Jan. 1st, 1898, of 3114, the largest annual increase we have yet had to record." The increase reported by the Commissioners had concerned all classes of patients, the private class to the extent of 2·73 per cent., the pauper class to the extent of 3·09 per cent., and the criminal class to the extent of 2 per cent. Of greater importance than the mere fact of increase is the fact that there is also an increase in the ratio of the insane to the general population, the advance being the small one of 0·4 per cent. in the private class, and of 0·59 per cent. in the pauper class. The total gives the ratio of one "officially known" lunatic to 302 individuals, as against one in 308 on Jan. 1st, 1898, and one in 337 on Jan. 1st, 1899 Attempts have been made to show that the increase is more apparent than real, that it is largely due to the accumulation of senile cases and to a diminished death-rate, and that there is no real increase of new cases; but when all is said there remain the undoubted facts that the numbers increase by leaps and bounds, that the county and borough authorities are constantly being confronted by the demand for more accommodation in county and borough asylums, that new asylums spring up as the result, and that the taxpayer has constantly to put his hand in his pocket to defray expenses. It will hardly be denied that such a condition demands that we should use every effort to diminish if possible at the source the numbers of those who thus become incapacitated either temporarily or permanently, who, if not possessing private means, become either a burden to their relatives or to the taxpayer, and who in some cases become criminals as the result of their mental disorder.

It would, of course, be quite impossible in the limits of time accorded by the rules of the Association to introductory remarks by presidents of sections to review all the causes of insanity and to cover the whole ground of their removal, but it seems to me to be profitable to draw attention to three items, viz., (1) the propagation of the race by those of insane inheritance or those who have suffered from insanity; (2) the influence of alcohol in the production of insanity and the need for preventive legislation; and (3) the causation of general paralysis by syphilis.

I.—THE PROPAGATION OF THE RACE BY PERSONS OF INSANE INHERITANCE OR WHO HAVE SUFFERED FROM INSANITY.

In Table XXV. in the report referred to above, giving the percentage of causes of insanity in patients under the cognisance of the Commissioners of Lunacy for the five years 1873-97 inclusive, hereditary influence was attributed as a cause in 20·4 per cent. of male and in 25·9 of female patients. These figures are well known to be far below what is the real proportion, and in Table XXVI., where the causes are reviewed in the two great groups of private and pauper patients, the percentages are found to be higher in the former, largely no doubt on account of the greater facilities for obtaining a history in that class; but even allowing that these figures are below the actual facts, we cannot escape from the fact that "hereditary influence" still gives the largest percentage of any of the causes enumerated by the Commissioners.

It cannot fail to be of the highest importance to the future of our race that the stock should be maintained in as healthy a condition as possible and should not be reproduced from defective individuals. This is fully recognised in the case of the lower animals, but human beings have a reluctance to apply the same rules to themselves. Nevertheless there can be no doubt that if we are to hold our own in the struggle for existence with other nations it is of the highest importance that the race should not be largely reproduced by individuals whose nervous system is so unstable that it very easily gives way under those stresses which must after all occur with great frequency in the various conditions of life, but should be propagated mainly by those who are abundantly well equipped from the nervous point of view. It will, no doubt, be thought that I am only giving utterance to a truism when I say that if the race were only reproduced by those of stable nervous system and sound by inheritance our existing asylums would soon be found to be larger than the

requirements of the population. In the last half of the nineteenth century enormous strides have been made in the care and treatment of the insane. They are infinitely better housed; their bodily and mental disorders are treated more assiduously and more scientifically, committees and unofficial visitors of all sorts take a much greater interest in and a much more humane view of their condition; their pathology is minutely inquired into; they are, thanks in great measure to the Medico-Psychological Association, infinitely better nursed; and after recovery such a society as the After-Care Association busies itself in helping the friendless victim of this most painful disorder again to take his place in the world. But I submit that with all this, which is most desirable and which exhibits all those qualities of sympathy with suffering for which our nation is so justly famed, very scant attention has been given to the question how a great deal of insanity can be avoided, and to the fact that a great deal of insanity is preventable and should be prevented. The Lunacy Law has been amended in the last few years so as to make it more difficult for those who urgently need care to be placed under care, while it has rendered it more difficult for patients to be detained and more easy for them to be discharged, as if the Legislature unconsciously arrived at the conclusion that by so doing it could diminish the numbers of the insane. There certainly was an impression among some members of the community, in spite of the denial of this by the Commissioners in Lunacy who are responsible to the public for the due discharge of patients from asylums, that large numbers of persons were detained on the very slightest pretexts, and it is thought by many that this impression weighed with those who were responsible for the drafting of the present Lunacy Acts. Nevertheless the numbers increase, and I submit that there is no more important problem for the twentieth century than the possibility of diminishing the numbers of the insane by their non-production. Among the more educated classes of the community there is, judging by the fact that those specially concerned in the treatment of mental disorders are often consulted on the subject, a recognition of the fact that the presence of insanity in a family at least demands from its members some serious reflection before marriage is entered upon, and it is often in the power of medical men to give advice which may, at any rate, prevent the union of two bad stocks. A short time ago I was consulted as to the rectitude or desirability of a marriage being contracted between a lady whose father had become insane about the time of her birth and had remained chronically insane since and a gentleman whose maternal aunt had been insane for 30 years. The gentleman would not agree to marry unless he could be assured that there was no risk whatever that his proposed wife would suffer from puerperal insanity in the event of a child being born, which assurance it was manifestly impossible to give, and also unless he were assured that there would be no risk of mental disorder in any offspring, which in view of the chronic insanity on both sides it was also impossible to give. Such a case shows that at least some members of the community have their eyes open to the fact of the importance of selection. Love is, however, proverbially blind, and among the unreflecting classes of the community nothing is thought of marriage with a person of insane inheritance. Unfortunately medical men themselves, unless they have had experience in an institution for the treatment of mental disorders, are not always sufficiently alive to the dangers of the propagation of the race from defectively constituted individuals and are sometimes apt to pooh-pooh any possibilities of risk in cases in which they are consulted and to give the opinion that there is no danger in a marriage between two persons of neurotic or insane stock provided the individuals themselves are apparently sound or have been so up to that time. It is perhaps well understood that in a question of marriage between cousins where there is insanity or any serious neurosis in a common ancestor or in the two separate families the idea of marriage ought not to be entertained but it is often overlooked that danger exists in the intermarriage of members of two families not related but where there is insanity or neuroses on both sides. It is very unlikely that the legislature will ever intervene to interpose any legal bar to marriage of individuals of insane inheritance; there will continue to be "free trade" in marriage as far as the law is concerned, but public opinion will have to be educated more and more to understand the importance of not propagating from bad stocks, and it is safe to lay down as a rule that no person of direct insane inheritance ought to marry with another of direct insane or neurotic inheritance, and that even if a person of stable inheritance proposes to marry with a person of insane inheritance, this latter fact of inheritance ought to be known and stated beforehand. In many cases this is done honourably, but in other cases the fact of insane inheritance of the most direct nature is concealed, on the one hand where large property is concerned, and on the other where, perhaps, there are several marriageable daughters in a family of limited means and where it is thought that the avowal of insanity in the family will "ruin their chances" as if the chief object in life were to propagate defective individuals. In other cases concealment takes place from ignorance or carelessness. In this, as in many other things, the greatest happiness of the greatest number must be thought of rather than the happiness merely of the individual, and there is the more honour to those who have relinquished what might have been a life of happiness rather than lend themselves to the degeneration of the race. With regard to the first heading, therefore, I conclude that it is the duty of the medical profession to give sound advice to those who consult them on this matter and not to lose sight of the fact that inheritance is the largest cause of insanity as shown by statistical tables.

If, however, there is doubt as to the marriage of persons of insane inheritance, there should be little doubt as to what ought to be the course and what ought to be the advice given in the case of persons who have themselves suffered from a definite attack of insanity, and in such cases marriage ought, as a rule, to be forbidden absolutely. Deplorable cases must be familiar to the minds of all those connected with psychiatry where patients who have recovered from a severe attack of mental disorder necessitating confinement in an asylum have subsequently married and either broken down again or propagated children defective from birth or breaking down at the critical periods of life. I remember well a patient in Bethlem Hospital who had great hostility to her parents, for which for a time I could find no explanation till one day she told me that what made her most angry was the fact that her birth had occurred subsequently to an attack of insanity from which her mother had suffered. Unfortunately, marriage with a person who has been insane is sometimes contracted by those who should by their education know better. For instance, I remember a patient in Bethlem who broke down in adolescence and eventually joined the large army of chronic dements whose father was a medical man who had married one of his patients who had recovered from an attack of insanity. In another case a nurse who was familiar with mental disease married a male patient who had temporarily improved but whose symptoms returned very quickly and led to a separation and much unhappiness. Fortunately there were no children of the marriage. She had taken this step against the advice of everyone who knew the man's condition. Again, a lady who had had several attacks of maniacal excitement and had been in Bethlem Hospital in one of them, married subsequently against advice and has only recently been discharged from Bethlem again, having broken down after the birth of a child. Such marriages as these are the surest way to increase insanity, but if they are sometimes entered into with a light heart by people of the educated classes it is not surprising that the more unreflecting classes should contract them freely. In the January number of the *Journal of Mental Science* of this year a deplorable case is recorded by Dr. C. C. Easterbrook, in which a girl of insane inheritance married after a fifth attack of insanity (which attack was a puerperal one following the birth of an illegitimate child) and subsequently had two children, after the births of each of which she again broke down mentally. I have no hesitation in saying that in some way or other such a patient ought to be prevented by law from reproducing her species. In all probability nature will speedily put an end to such a bad stock, but it may be at great cost to the community first. Another case occurs to me in which a young girl who had broken down acutely after the death of her lover recovered in a few months and within a year had found another young man to marry her. The marriage was undertaken against advice and within six months after marriage she had broken down again. In such cases the popular idea is that the patient is sure to be all right when she is married and that the insanity is due to the celibacy, and medical men even have not always the strength of mind to inform the relatives

that the likelihood of insanity after childbirth, if not at any other epoch, is greater in such cases than the likelihood of stability.

A great difficulty is presented in the case of those who break down subsequently to marriage but recover, and where the woman is still of child-bearing age. It is impossible to go deeply into this matter, but it is an important question when, for instance, a woman has had puerperal insanity after the birth of her first child whether she ought further to reproduce her kind. The answer to this, in my opinion, depends largely upon whether the puerperal attack depended simply upon what may be called an accident, as, for example, some septic condition, or whether it is merely the expression of an inherited neurosis which first appears at the puerperal epoch. In the latter case one feels that it would be best that the woman should cease child-bearing; but here again it is impossible to do more than advise to that effect, the advice given being in most cases not followed. In the case of a woman who has a puerperal attack after the birth of each child there can be no doubt of the unsatisfactory nature of the children she is bringing into the world and that such a bad stock ought not further to be reproduced, but how to effect this except by advice is difficult to see. The new civil code in Germany enacts that continuing insanity of over three years in duration is a ground for divorce, but I apprehend that in this country such a measure would have no chance of being placed on the statute-book in view of the fact that recovery may take place after a longer period than that, that where there are children their position would be rendered socially unpleasant, and that marriage is "for better or worse" and that the accident of disease should not be allowed to absolve a husband of his obligations. There is no doubt, however, that some such enactment would assist in putting an end to the chance of reproducing a bad stock.

It might be thought superfluous to comment on the iniquity of a congenital imbecile being allowed to marry were it not that several cases are recorded in which this has taken place where large property is concerned and with, of course, deplorable results to the offspring. Again, marriage ought not to be permitted in the case of chronic epileptics, whether the disorder be of the nature of *petit mal* or *grand mal*.

II.—THE INFLUENCE OF ALCOHOL IN THE PRODUCTION OF INSANITY.

Next to heredity alcohol figures most largely in the causes of insanity given in the Commissioners' tables, accounting for 22 per cent. of the male and 9·1 per cent. of the female cases. This refers to the effect of alcohol on the individual alone and takes no note of alcoholic inheritance as leading to the production of insanity, idiocy, alcoholism, hysteria, epilepsy, or other neuroses in the offspring, though it is well known to act in this way. This large percentage of what may well be looked upon as a preventable cause of insanity ought to give the Legislature profound heart-searching as to whether it is doing its duty to the community in checking the ravages of this destructive poison. I shall not be contradicted when I say that the percentages above quoted do not represent anything like the real amount of damage which is done to the nervous systems of the community by alcoholic excess. In addition to the actual numbers who are sufficiently poisoned by alcohol to be certified as insane, there are large numbers of individuals who are from time to time dangerously unsound, it may be for a few hours or a few days, who are the terror of their relatives, who form a large proportion of the cases at police-courts, and who ruin themselves in health and fortune. And those who have had charge of the insane will agree with me that the cases of mental disorder due to alcohol are among the most difficult to manage, the most hostile and litigious, and after recovery very often the most ungrateful of any patients with whom we have to do. No doubt in many cases the alcoholic is a person who starts life with an unstable nervous system; he has either an alcoholic or an insane or a neurotic inheritance, and to a certain extent he is defective *ab initio* in self-control and goes without much resistance into the paths of chronic alcoholism, but at present the Legislature has given him no assistance. The facilities for drinking are enormous and the revenue of the country largely depends upon the quantity of alcohol consumed.

As long ago as 1893[1] a memorial signed by many members of the medical profession urging the enactment of compulsory detention for inebriates was presented to a Departmental Committee appointed by the Home Office, but the only outcome of movement in that direction has been the Inebriates Act of 1898, upon which Mr. Wood Renton[2] remarks: "The first point that calls for observation is that in spite of the unanimous demand for them on the part of every Parliamentary Committee that has inquired into the subject during the last quarter of a century ..... no powers for the compulsory committal of non-criminal inebriates have been brought into existence by the new statute." The new powers for dealing with criminal inebriates, moreover, have been almost a dead letter in consequence of the supineness of local authorities, though it is satisfactory to see that the London County Council is at last alive to its responsibilities in this respect. The report of the Royal Commission appointed to inquire into the operation and administration of the laws relating to the sale of intoxicating drinks, published in 1899, recommends that simple drunkenness should render an individual liable to arrest, that it should be penal to serve habitual drunkards with liquor, and that habitual drunkenness should be treated as "persistent cruelty," entitling a wife or husband to separation or protection for herself, himself, or the children. Unfortunately, however, the present Government seems disinclined to take the subject in hand. That such protection is frequently needed by the relatives of those who become maniacal from drink is undoubted, and there are few histories more sad than those told by the wives of the alcoholic insane, in which for a long time before it has become necessary to take steps under the Lunacy Acts there has frequently been recurring excitement, brutality, and danger to wife and children, with gradually increasing poverty and loss of social position. In a note on the report in the *Journal of Mental Science* for January, 1900, the following remarks are made: "The Commission does not seem to have troubled itself with statistics with regard to the share of intoxicants in the production of mental disease." There need have been no difficulty in this respect, as it is only necessary to look at the tables in the reports of the Commissioners in Lunacy, or in any asylum report, to see that between one-fourth and one-fifth of the male cases of insanity admitted annually to asylums are attributed to alcohol. Dr. T. S. Clouston, in the report of the Morningside Asylum for 1899, speaks of alcoholic excess having been the cause of insanity in 25 per cent. of the cases admitted. He remarks that few persons who had had an opportunity of studying the effect of alcohol on the brain would not heartily approve of most of the recommendations of Lord Peel's Commission. The Inebriates Act of 1898, he points out, has done very little good, and if there is to be legislation on the subject it should be effective. Even those who hold the liberty of the subject so sacred as to wish to leave the alcoholic to drink himself to organic disease or insanity and his family to poverty might at least turn their attention to the fact that nearly a quarter of the insane are so, either wholly or in part, from a preventable cause, and that in a large proportion of these cases the ratepayer has to bear the expense.

Closely related to this subject is the question of the relation of suicide to alcoholism. In a paper by Dr. W. C. Sullivan, deputy medical officer of Her Majesty's Prison, Pentonville, in the April number of the *Journal of Mental Science*, attention is drawn to the increase of suicide and of suicidal attempts concurrently with recent increase of alcoholism. He points out that the recent increase of suicide has coincided with a considerable increase of abortive suicidal attempts which have approximated to the type of alcoholic suicide in being more impulsive, more related to organic conditions in the individual, and occurring at an earlier average age than suicide from other causes. If his views be correct it is evident that alcohol is thus responsible for the loss to the community of many valuable lives in the period of early adult life. I hold, therefore, that it is our duty as medical men concerned with the care of the insane to point out, amid all the outcry about the increase of insanity, that with regard to alcohol at least there should be an opportunity, with proper legislation, of preventing a good deal of insanity, and that this Association should continue to urge the necessity of further legislation to check the ravages of that seductive but destructive poison.

III.—THE CAUSATION OF GENERAL PARALYSIS BY SYPHILIS.

There can, I think, be very little opposition now to the statement that acquired syphilis is one of the most potent

[1] Journal of Mental Science, April,

[2] Ibid., April, 1899.

predisposing causes of general paralysis. While some observers hold that in every case of general paralysis, if the history be carefully taken, some evidence of syphilis will be found, the great majority recognise at least that even if a history of syphilis cannot always be obtained at any rate such a history is to be found in cases of general paralysis very much more frequently than in any other forms of mental disease. I intend to regard this preponderance of a history of syphilis in cases of general paralysis as an established fact and to lay down the proposition that if there were no syphilis there would be very little general paralysis. According to the report of the Commissioners in Lunacy for 1898 the yearly average number of general paralytics admitted to asylums, hospitals, and licensed houses amounted to 13·1 per cent. of the male cases and 2·8 per cent. of the female cases (Table XXIII.), while general paralysis was the cause of death in 1057 males out of a total of 4065, or more than one-fourth of the total male deaths, and in 265 females out of a total of 3513. Evidently in males at least general paralysis is a most serious cause of death in asylums, and moreover it kills those chiefly who are in the prime of life. It is, therefore, most important that no stone should be left unturned to stay this waste of life. It is well known that general paralysis occurs most frequently in towns where syphilis, alcohol, and fast living are most rife, and no doubt one of the most important measures is to train the dwellers in towns in habits of self-control and to teach them to lead physiological lives; but there seems no reason why the Legislature should not take some steps to check the spread of such a potent poison to the nervous system as syphilis as it has already done in the case of the infectious fevers. It was formerly held that the general paralytic did not transmit the disease to his children, but in the last few years many cases have been recorded of "juvenile general paralysis," in practically all of which there had been found to be a history of parental syphilis,[3] and in many of these cases the father had previously died from general paralysis. It cannot be said, therefore, that the syphilitic general paralytic is not a danger to his offspring, and so a further waste of valuable lives takes place. In my opinion, if syphilis were made a notifiable disease and the chances of its spread diminished, we should see a corresponding diminution in the number of cases of general paralysis. I am well aware that any suggestion to control syphilis, or in fact any venereal disease, by legislation meets with opposition from a section of the community, but it is well to refer to the fact that in Finland, as the result of the hospital treatment of syphilis and the power given by the Legislature enabling the compulsory examination of any suspected individual, syphilis has much diminished in the course of 20 years, that congenital syphilis has become less frequent, and that both the hereditary and acquired forms have become of much milder type.[4] Dr. Drysdale,[5] in a paper on the "Norwegian Bill for the Prevention of Venereal Diseases," calls attention to the existing law in that country requiring practitioners to notify the existence of any case of venereal disease to the medical officer of health but without giving the name of the patient, and suggests that such simple notification would at least "for the first time in the history of these contagions, afford a basis for calculation of the extent to which they prevail among the population of the United Kingdom." He further says: "Eventually I believe that the danger to public health caused by these extremely prevalent contagions will result in punishment of persons who, knowing themselves to be infected, carelessly, or even without any compunction, are heartless enough to put themselves in the way of infecting other persons with their contagion." In my opinion general paralysis should be looked upon as a preventable disease, and I feel strongly convinced that were syphilis controlled this truly malignant degenerative disease of the nervous system, which at present seems to defy all treatment, which adds so largely to the deaths in asylums, which mainly affects men in the prime of life, and which may also affect their children by means of hereditary syphilis, would to a great extent disappear. In all probability, however, the public mind is not prepared for any legislation on the subject.

I have merely attempted to call attention briefly to what I consider to be preventable causes of insanity, and of the importance of prevention rather than cure I think there can be no doubt. Whether the ensuing century will be marked by an arrest of insanity at its sources is, however, a matter on which we cannot speak with any certainty, but it seems to me to be the direction in which our efforts should tend.

THE REMOTE RESULTS OF STRUCTURAL LESIONS ("INTERVENTIONS SANGLANTES") IN URETHRO-STENOSIS.[1]

BY REGINALD HARRISON, F.R.C.S ENG.,
SURGEON TO ST. PETER'S HOSPITAL FOR STONE AND GENITO-URINARY DISEASES.

I HAVE been asked to report to this Congress on the remote effects of structural lesions (*interventions sanglantes*) employed in the treatment of stricture of the urethra. I think it will be generally admitted that these results are mainly determined by the nature of the wound and the circumstances under which it healed. For instance, incised and contused wounds and wounds that heal without any or with much inflammation, or with little or no provision for drainage, may be expected to yield different results. For this happens in all parts of the body. But in estimating the results of structural lesions of the urethra we must never lose sight of the fact that this canal conveys for several inches, at varying intervals, a compound and complex fluid which, under certain conditions not very clearly defined, is capable of exercising a highly poisonous effect on the tissues and fluids of the body with which it may accidentally come in contact. This is evidenced by the frequency of rigors and fever not unlike a malaria after slight lesions, such as passing a catheter or dividing a stricture, by the sudden suppression of urine which is sometimes similarly occasioned, by the happening of serious, if not fatal, septicæmia later, and more remotely by the formation of a contractile scar at and about the seat of the wound. Surely we may say that the pathology of the urethra is a unique one.

To compare their results it will be necessary to define with some accuracy the kinds of wounds that preceded and their probable process of healing. For the purposes of this report the following varieties have been examined and carefully studied both during life and, as opportunity offered, after death: (1) lacerated or contused wounds as follow such methods of divulsion as were practised by Perrève[2] in Paris and Holt[3] in London; (2) incised wounds from within the urethra as illustrated by Maissonneuve's[4] and other kinds of internal urethrotomy; and (3) incised wounds from without inwards as described by Syme[5] of Edinburgh under the name of "external urethrotomy" or perineal section.

1. Wounds inflicted by instruments for rapidly causing divulsion or rupture of a stricture are usually of a contused or lacerated character. When thus employed, unless the stricture is an annular or a ring-like one, a condition which is rare, the canal usually gives way at a point in its circumference where the resistance is least, and this is naturally not the densest portion of the contraction. Hence these operation wounds heal not unlike accidental lacerations of the urethra from injury, and in both instances the liability to stricture and to its recurrence is considerable. This was found to be so in cases examined both during life and after death and repeated operations by divulsion appear to have been followed by additions to the amount of contractile scar-tissue at or about the seat of stricture. There is, however, a form of stricture where divulsion is not open to these objections as judged by its more remote effects. Reference is here made to what are known as peri-urethral or sub-mucous strictures. My attention was first called to them some years ago by examining a patient who died from some other cause shortly after (within a week) a tight stricture in the deep urethra had been

[1] A paper read before the Thirteenth International Congress of Medicine in Paris on August 8th, 1900.

[5] On the Treatment of Strictures by External Incision, 1851.

divulsed by Holt's method. The stricture was found to be peri-urethral and it thus compressed the mucous coat as a ligature round it would do. The effects of the divulsion had been to rupture the fibres of the stricture whilst it left the mucous lining almost intact. Mr. Christopher Heath [6] has also recorded a similar observation. I am inclined to think that the consequence of its casual application to this class of cases and the excellence of the results was that Holt's operation attained a position regarding the treatment of strictures generally which it hardly appears to have merited. No better result relative to the permanency of the cure can be desired than this and if it were possible to limit divulsion to peri-urethral strictures I believe this operation would still be frequently employed. I have examined several urethras many years after Holt's operation had been performed where the canal had maintained its full measurements and no trace of a lesion of the mucous membrane could be found. We may claim these as instances of the successful treatment of stricture by subcutaneous, or rather submucous, methods.

2. The remote effects following internal urethrotomy are of a variable character, arising mainly from the nature of the cicatrix or scar-tissue that follows the operation. In some instances I found from examination after death several years afterwards that no signs of the original stricture were discoverable either in the mucous membrane itself or in the submucosa. As far as I could ascertain the incision made by the urethrotome had soundly healed without leaving any mark or contraction. As illustrating this class of cases I will select one that has recently come under my observation where the previous history was well authenticated throughout. It was that of a man, aged 53 years, whom I saw in February, 1900. He was operated upon in 1883 by the late Mr. Berkeley Hill for a stricture in the deep urethra which would only then admit a filiform bougie. Internal urethrotomy was performed. I saw and examined this patient with Mr. C. B. Lockwood, who had been personally aquainted with him throughout. I could find no evidence of stricture. The patient had ceased to use a bougie for some years. There could be no question that this man had been permanently cured by the operation.

On the other hand, the majority of instances examined showed in varying degrees that a tendency to relapse occurred within a few weeks or months after the operation, even where patients had endeavoured to prevent this by the use of a bougie. In these, for the most part, there were signs that the wound inflicted had probably been an irregular or jagged one, more resembling a lacerated wound than an incised one, and not what would be expected from a well-constructed urethrotome. Further, the resulting cicatrix often presented an appearance not unlike what happens after a burn of the second or third degree, or as I have seen following electrolysis for stricture.

In some instances of recurrence after internal urethrotomy it was apparent that this operation had only partly divided the stricture. From the evidence that was afforded by this class of cases it was concluded that the combination of partial incision of a stricture by internal urethrotomy, followed immediately by stretching of the wound thus made by divulsion or bougies, did not yield good permanent results. It was in some of these cases that recurrence took place most speedily and in an aggravated form.

3. The third group of cases examined were those where the stricture was divided from without inwards on a grooved staff in accordance with Syme's description of external urethrotomy or perineal section. In several instances where this operation had been practised some years previously I found no recurrence had occurred, though the use of a bougie had practically been discontinued. I have recorded [7] a case where a patient, aged 46 years, had been operated upon by external urethrotomy for stricture and urinary fistulæ by a former colleague of mine in 1867. He died 18 years afterwards, and on examining his urethra I could find no sign of stricture. The dimensions of the canal along the line where the section had been made were larger than the rest. The patient had not been in the habit of using a bougie since the operation.

It will not be necessary further to illustrate the permanent advantages that have followed perineal section in some cases of urethral stricture. In restoring and preserving the normal dimensions of the canal and in rendering catheterism easy where previously it was difficult its advantages must be apparent in cases to which it is applicable, and these include some of the worst varieties of stricture. If performed without a guide the prospect of a good result is very small. Where practised successfully it was not easy to determine how much of the permanent good that resulted was due to the complete division of the stricture and how much to the drainage which the external wound provided; but it seemed probable that both contributed to this end.

Taken as a whole, these investigations support a conclusion that most strictures treated in the three ways referred to, showed a tendency to re-contraction in varying degrees. In some this liability was easily counteracted by the use of bougies after the operation, though practically it could not be said that there was any time limit to this expedient. In others the tendency to relapse was so rapid and strong as to require repeated operations to maintain the dimensions of the canal, or even to necessitate the formation of a urinary fistula in place of the urethra. In a few instances, after rapid divulsion, internal urethrotomy, and perineal section or external urethrotomy, the evidence was conclusive that a permanent cure had resulted, and in such cases the subsequent use of a bougie appeared precautionary rather than necessary. It must, however, be stated that, compared with the large number of stricture cases which were investigated for this purpose, and where the observations extended over a considerable number of years under favourable circumstances for conducting such an inquiry, the instances last mentioned were rare. These conclusions will, I think, correspond with the experience of most surgeons.

I take it that the object of this report is not merely to reiterate a foregone conclusion but to explain, if possible, how these variations may have happened, and how both good and indifferent results may alike contribute to advance knowledge in connexion with this subject. In examining the lesions thus made for the treatment of certain forms of stricture by urethrotomy, and I include both varieties of operation under this term, it was evident that some of them had been faulty in their application and in their construction relative to the process of healing which would follow. In a few instances appearances indicated that the incision or incisions had not been accurately applied to the constriction, that the urethrotome had lacerated rather than cut, that several wounds had been made in various directions, and thus by scar-tissue the obstruction was rather added to than lessened by what had been done. This was probably directly due to faulty instruments in the case of internal urethrotomy and to want of precision and completeness in carrying out the details of perineal section. Though some failures may be accounted for in these ways, more were evidently due to the conditions under which healing proceeded after the operation. Many of the incisions that were made for the purposes of internal urethrotomy were inadequately provided with means for proper drainage, having regard to their extent, whilst some cases of perineal section or external urethrotomy were hardly any better off in this respect.

About the time I commenced to make these observations on a somewhat extended scale internal urethrotomy was being practised with a very free hand. The late Professor Otis of New York had recently formulated his views relative to the male urethra which to some extent were responsible for this. Though fully recognising the value of his work in demonstrating the greater capacity of the male urethra and the important influence that this had on the new lithotrity or litholapaxy which Bigelow was developing in the wake of Otis's investigations, I could not follow him in the practical application of it, in its entirety, to the treatment of stricture. However, it tended in the direction of increasing the range of internal urethrotomy as well as the size of the wounds thus made, but I cannot say that it proportionately added to the number of cures in chronic stricture of the deep urethra. It struck me in examining cases which had been thus operated on some years previously by various surgeons where the stricture had recurred that the size or depth of the wound so made was out of proportion to the facilities for drainage, whilst healing was going on, which the urethra alone afforded. In the absence of the latter condition I recognised one reason for the contractile condition of the scar that resulted. In arriving at this conclusion I was much influenced by what I had observed in connexion with the treatment of accidental lacerations of the deep urethra by perineal incision and drainage.

It may be generally stated that the worst forms of strictures are those following laceration of the urethra, and considering the circumstances under which such lesions usually heal this is not to be wondered at. Repair goes on slowly under the

[6] Brit. Med. Jour., July 17th, 1869.
[7] Surgical Disorders of the Urinary Organs, fourth edition, p. 100.

irritating influence of constant contact with confined urine, and excessive exudation about the seat of the wound takes place. This eventually, in conjunction with the irregularity caused by the wound, forms a stricture of the closest and most contractile character. On the other hand, in cases where perineal section and drainage were applied, this either did not happen at all or to a much more limited extent. In some instances where this principle was adopted in the case of ruptures of the deep urethra, healing took place just as kindly as it usually does after a median cystotomy, and no stricture followed. This I proved in many instances. It seemed reasonable to conclude that the treatment of stricture by section, or division of the stricture, might be improved by providing better drainage for urine and the discharges from a wound which can only be imperfectly treated antiseptically.

I am not aware that the influence of urine-drainage and irrigation in relation to the healing of wounds of the urethra and the kind of scar-tissue that results have ever been adequately discussed in connexion with the operative treatment of urethral stricture. With the view of meeting what I consider to be causes of failure and recurrence following some operations, I published[8] a series of cases and observations where I had combined the principles of internal and external urethrotomy in the treatment of certain forms of urethral stricture which on the whole have afforded good results. I shall best illustrate this practice by a typical case which was recorded and watched for a considerable number of years.

A man, aged 51 years, whom I saw and operated upon in 1890, had been the subject of a stricture with a strong tendency to contract for some years, and had undergone no less than six operations for it, including a divulsion by Holt's method, and five internal urethrotomies at various intervals and places. For some months before I saw him the stricture had been contracting and closing in spite of the patient's well-directed efforts with suitable bougies to keep it open. Straining to urinate was constant and prevented continuous sleep, and there was some cystitis with probably pyelitis. I performed an internal urethrotomy with Teevan's modification of Maissonneuve's instrument, as I thought that the latter might not stand the strain put upon it by the cartilaginous character of the tissues which had to be divided. This being done I passed a full-sized grooved staff (No. 12 English) into the bladder. As the staff was evidently gripped in the deep urethra the patient was placed in the lithotomy position and I divided in the median line from without inwards such contracted tissues as remained. I thus opened the urethra and found by passing my finger first into the bladder and then hooking it forwards along the urethra in the direction of the penile orifice that the walls of the canal had now been rendered free and unresisting. A full-sized gum-elastic drainage-tube such as I have elsewhere described[9] was passed into the bladder through the wound and retained. The parts were washed out with a solution of perchloride of mercury (1 in 6000). The stiff drainage-tube was withdrawn on the sixth day and a soft rubber one fitted with a tap for the voluntary withdrawal of urine was substituted which was worn for a fortnight longer and then finally removed, when the wound soon healed. Ten years have now elapsed since this operation was practised. The patient remains in good health and suffers no further inconvenience from his urinary organs than having occasionally to pass a full-sized bougie for himself.

It may be thought that the retention of a catheter in the bladder for some time after an internal urethrotomy has been practised is to be preferred to an external urethrotomy, and a perineal tube for drainage alone. In some instances the former may suffice, but in the majority of cases where a urethrotomy becomes necessary it will be found an imperfect substitute. The mechanism for the retention of a catheter along the whole length of the urethra and the irritation it excites are often obstacles to the successful employment of this expedient.

The conclusions arrived at from the examination of structural lesions used in the treatment of urethral strictures as detailed in the foregoing remarks may be summed up as follows.

1. That there is evidence to show that in peri-urethral strictures of the deep urethra the effects of divulsion as practised in Perrève's and Holt's operations may be limited to rupturing the dense stricture bands in the submucosa of the urethra, whilst the mucous membrane itself escapes any serious injury or laceration and is merely restored by stretching to its original dimensions. Here a permanent cure may result. On the other hand, where the mucous membrane is in itself the seat of stricture and forms part of the latter structurally it is necessarily torn or lacerated by the process of a sudden divulsion, and the pathological condition consequently becomes assimilated with that of traumatisms of the urethra from external violence accidentally applied which are followed by strictures of the most contractile and recurrent form.

2. That there is evidence to indicate that where the entire thickness of a stricture can be included within an incision of moderate dimensions made by an internal urethrotome the normal calibre of the urethra may be completely and permanently restored. Where this happens it may be concluded that all the fibres of contraction constituting the stricture were divided at the time of operation. And further that the converse is equally true. There is also evidence to show that the absence of recurrence under such circumstances is not necessarily dependent on the use of a bougie, though the latter is a precautionary measure which should invariably be advised.

3. That in the case of multiple strictures or strictures of the deep urethra of considerable dimensions either in their length or thickness treated by an internal incision of corresponding proportions, apart from other considerations, the tendency to recontraction and recurrence, with an additional amount of cicatricial material, is frequent; the latter being probably due to the circumstances under which healing takes place in wounds of these dimensions so situated.

4. That lesions of the urethra demonstrate in various ways the poisonous effects that unprotected and confined urine is capable of exercising both on the body generally and on the tissues in contact with it, and that the liability to such effects is greatly diminished where drainage and irrigation render these conditions of the urine unlikely.

5. That in the case of recurring strictures previously treated by incision and in primary strictures of such length or extent as to require an internal section of a corresponding size, or as to which there might be doubt as to whether it would be safely possible so to include them, for the purposes of the operation and its results such wounds should be made with due regard to other surgical principles in addition to the one pertaining to the division of the contraction.

6. That there is direct evidence to show that the tendency to recontraction and recurrence of stricture after internal urethrotomy is largely diminished by the concurrent employment of systematic and efficient urine and wound drainage such as the combination of external urethrotomy, or perineal puncture, affords.

THE INDICATIONS OF THYROTOMY.[1]

BY SIR FELIX SEMON, M.D. BERL., F.R.C.P. LOND.,
PHYSICIAN FOR DISEASES OF THE THROAT TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

WHILST it is in the nature of things that thyrotomy can never be an everyday operation, it cannot be gainsaid, I think, that hitherto it has additionally been anything but a popular one. The reasons of this are not far to seek. Previously to the invention of the laryngoscope the indications of opening the larynx were so very obscure that the number of thyrotomies known to have been performed in pre-laryngoscopic times is exceedingly small.[2] When with the introduction of the laryngoscope a period of greater activity and wider applicability seemed to be in store for thyrotomy a very formidable rival to it arose almost immediately in the shape of intra-laryngeal surgery. This rival vigorously, and on the whole victoriously, contested the

[1] A paper read before the Thirteenth International Medical Congress in Paris.

[2] With regard to the history of the operation, and indeed with regard to all details concerning the operation itself upon which I am unable in the limited time at my disposal to enter, I would refer to the excellent monograph on Laryngotomie written by Professor Max Schüller of Greifswald in Billroth and Luecke's Deutsche Chirurgie (Stuttgart, Ferdinand Henke, 1880).

propriety of the external operation with regard to two of its most important indications—viz., the removal of foreign bodies and the removal of benign new growths from the larynx—and succeeded in limiting its performance in these classes of cases to a very insignificant number. Shortly afterwards another of the most important indications of thyrotomy—its performance in cases of malignant disease of the larynx—was strongly assailed by Professor Paul Bruns in his well-known monograph, "Die Laryngotomie zur Entfernung endolaryngealer Neubildungen."[3] The conclusions which he drew from the statistical survey of the thyrotomies which had until then been performed for the removal of cancer and sarcoma were so convincing and at the same time so adverse to the performance of the operation that they were tantamount to its complete condemnation in cases of that sort. Only quite recently has the operation begun to recover its position. At present an era of far greater usefulness is, I believe, dawning for it, particularly in certain cases of malignant disease of the larynx. I shall be glad if the proposals which I am going to make and the discussion which will follow should contribute towards that goal.

Two short remarks are required before I enter upon my subject proper. 1. In discussing nowadays the "indications of thyrotomy" it is imperatively required to discard from one's mind antiquated notions about its dangers and drawbacks. The number of improvements in the technique of the operation itself and of its after-treatment, on which my friend and co-reporter, Professor Dr. Schmiegelow, will no doubt dwell in his introductory remarks, have done away with many of the objections which only 12 years ago were justified enough. It is therefore possible at present to recommend the performance of thyrotomy under circumstances in which in previous times such recommendation would have been unjustifiable. 2. In speaking of the "indications of thyrotomy" it must always be kept in mind that, with a few exceptions, the indications of this operation are not *compulsory* but merely *facultative*. In other words, in the great majority of circumstances in which the performance of thyrotomy comes into question other means of dealing with the case in question may be substituted.

The indications, then, which at the present stage of our knowledge present themselves to my mind for the performance of thyrotomy are: (1) foreign bodies in the larynx; (2) injuries to the larynx; (3) laryngocele; (4) stenosis of the larynx; (5) acute laryngeal perichondritis; (6) laryngeal tuberculosis (including lupus); (7) scleroma of the larynx; and (9) new growths in the larynx—(*a*) benign, and (*b*) malignant.

1. *Foreign bodies in the larynx.*—I do not think that there will be much divergence of opinion as to the mode of procedure in the event of a foreign body having been impacted in the larynx. Should the foreign body be comparatively small, not too angular, not possess many sharp hooks and edges, and not cause any respiratory difficulty, everybody nowadays will probably in the first place attempt to remove it *per vias naturales*. Should this be impossible on account of the size or the form of the foreign body, or of its firm impaction in the soft laryngeal tissues which might lead to their being lacerated in the event of forcible intra-laryngeal removal, or should œdema or considerable dyspnœa be present, either tracheotomy ought to be performed and an attempt be made to dislodge the foreign body from the tracheotomy wound, or subsequent intra-laryngeal attempts at removal might be made, or finally, thyrotomy might be at once performed. In this question no dogmatic rule can be laid down; every individual case must be treated on its own merits. There is one point, however, with regard to which a note of special warning must be sounded. Under no circumstances is it advisable to allow a foreign body to remain impacted in the larynx for any length of time even if at first it does not produce any serious symptoms. I have seen and recorded several cases in which a neglect of that kind led either to perichondritis, ankylosis of the crico-arytænoid articulations and lasting disablement of the organ, or to the sudden dislodgment of the foreign body and its entrance into the lower food and air passages, with serious consequences resulting.[4] Considering that thyrotomy in a healthy person is at present an operation of but small risk I should not now, if my attempts at intra-laryngeal removal failed or if the case from the first were not suitable for this method, hesitate to perform thyrotomy with or without preliminary tracheotomy according to the special requirements of the case.

2. *Injuries to the larynx.*—In cases of severe fracture of the larynx, bullet-wounds, or suicidal injuries it has been repeatedly proposed to perform thyrotomy in order to replace the dislocated fragments, and, if necessary, to retain them in position by a tube introduced either through the mouth or from the tracheotomical opening. The reasonableness of this indication cannot be doubted, and the operation has been performed in a few cases with excellent results, but the indication, needless to say, is likely always to remain a rare one.

3. *Laryngocele.*—Laryngeal air-cysts, themselves extremely rare, still more rarely cause serious symptoms. In a case described by Benda and Borchert,[5] however, sudden inflation of a laryngocele ventricularis caused death by asphyxia. Should the symptoms, therefore, be threatening, thyrotomy followed by extirpation of the cyst would be indicated, as already successfully practised by Ledderhose.[6]

4. *Thyrotomy in stenosis of the larynx.*—It is likely that thyrotomy will be performed more frequently in cases of stenosis of the larynx than hitherto when once the still prevailing impression has been corrected that thyrotomy is a risky and difficult operation. Any of the manifold causes of stenosis of the larynx—cicatricial contraction from ulceration of the mucous membrane; perichondritis, particularly of syphilitic origin; hyperplastic inflammatory processes; congenital webs; adhesions between the vocal cords, ventricular bands, or other parts of the larynx, from external wounds, scalding, syphilis, typhoid fever, and a host of similar causes—may produce considerable narrowing, or even complete obliteration of the larynx. A number of these conditions will be, no doubt, accessible to intra-laryngeal surgery. In another class intubation by either Schrötter's or O'Dwyer's tubes, when patiently used, will be productive of excellent results; but a number of cases will remain in which neither of these two methods can be made use of at all or in which, for external reasons, it is impossible to continue it for a sufficiently long time to prevent re-formation of the narrowing, a contingency which, it is well known, is unfortunately but too frequent. It is in this class of cases that I think there is a future for thyrotomy. Particularly in cases of hypertrophic stenosis, with enormous fibroid thickening of the mucous membrane, excellent results may be obtained, as I have twice seen in cases operated upon by this method in St. Thomas's Hospital by thyrotomy and bold excision of the hypertrophic masses. Hitherto such cases have remained either entirely unrelieved, the patient having to wear a tracheal cannula for the rest of his life and his voice being reduced to an almost inaudible whisper, or patients have had to undergo an intubation treatment extending over many months with the penalty attached to it that even a short interruption threw them back to the very beginning. Thyrotomy in suitable cases undoubtedly relieves more quickly, but here again I need not say that I do not recommend a wholesale performance of the external operation, but think it must be left in every individual case to the judgment of the medical attendant which method—intra-laryngeal operation, intubation, or thyrotomy—is most likely to lead to a satisfactory result. It also ought to be clearly understood that in some cases of great fibroid obstruction of the interior of the larynx, particularly of syphilitic origin, even if the result of thyrotomy at first be all that can be desired, occasionally renewed thickening takes place, sometimes after the lapse of a year or more. A case of this kind was recently shown by Mr. Spencer before the Laryngological Society of London.[7]

5. *Acute laryngeal perichondritis.*—The indications for thyrotomy in acute laryngeal perichondritis, in spite of Schüller's warm recommendation,[8] have never been generally accepted and are likely to remain extremely rare. According to Schüller, thyrotomy ought to be performed already in the first stage as well as in the further course of perichondritis in order to treat the perichondritis itself through the laryngotomical opening in a suitable manner—i.e., by

incision, extraction of necrotic parts of cartilage, and aseptic treatment of the perichondritic abscess. Unfortunately, it is very difficult, and likely to remain so, in many cases of acute perichondritis to say definitely which cartilage is the actually diseased one, and the fear of producing by the performance of thyrotomy additional undesirable complications is more than a theoretical one. Occasionally, however, as in a case of my own,[9] real good may accrue from thyrotomy being resorted to in time in acute laryngeal perichondritis, and its performance in this class of cases deserves, I think, to be more frequently thought of than apparently it is at present.

6. *Laryngeal tuberculosis (including lupus).*—Of late years thyrotomy has been repeatedly performed in cases of laryngeal tuberculosis, and Dr. Goris, who has probably paid more attention to this subject than anybody else, has formulated its indications as follows.[10] "Thyrotomy," he thinks, "is optional in circumscript lesions, and even preferable in tubercular patients whose general state of nutrition is good, even if their lungs should be much affected. It is not desirable in tubercular patients, whose state of health is bad, or whose whole larynx is deeply affected." Undoubtedly cases occur in which intra-laryngeal surgery does not succeed in removing by curetting or similar proceedings even circumscript laryngeal tuberculous lesions, because they are not favourably situated for intra-laryngeal interference. In such cases if the general state of health be good thyrotomy would be entirely legitimate and, as Dr. Goris's results and one obtained by myself show, laryngeal lesions in such cases may be lastingly cured by that operation. There is, however, one very serious drawback to the employment of thyrotomy in this class of cases which ought to be before the mind of every operator—viz., the danger of tuberculous infection of the wound. In my own case just referred to, in which I performed thyrotomy, the laryngeal lesion was quite cured after thyrotomy had been performed, the ulcerating surface removed, its bottom scraped, and pure lactic acid applied, and the cure remains permanent now—i.e., fully three years after the operation. But this satisfactory result was at first greatly marred by the external wound becoming tuberculous and fistulous tracts forming all over in front of the larynx and the trachea. Finally reopening of the old scar and an extensive operation became necessary in order to thoroughly remove the parts which had become infected with tuberculosis in the course of the operation. At the time I thought that this was a very exceptional surgical misfortune. On studying, however, Dr. Goris's valuable contribution just referred to I found that the same mishap occurred in all his four cases, and it seems, therefore, legitimate to conclude that tuberculous infection of the wound is a danger which must be seriously reckoned with in this class of cases.

As to lupus of the larynx, thyrotomy has, so far as I know, but once been performed for that disease. In the "Handbuch der Practischen Chirurgie," by von Bergmann, Bruns, and Mikulicz, I see it stated that Brondgeest has obtained a cure in a case in which he performed sub-hyoid pharyngotomy combined with laryngotomy.

7. *Scleroma of the larynx.*—In this rare affection thyrotomy, occasionally to be followed by methodical dilatation, appears to be the sovereign operation. Pieniazek, according to his own statements,[11] has performed the operation in no less than 130 cases, "mostly on account of laryngo-scleroma, and considers it the quickest and most reliable method of dealing with this troublesome disease." Recurrences are not excluded but seem to occur much later and in longer intervals than after the use of other methods.

8. *New growths in the larynx.*—(*a*) Benign growths.—The principle for the removal of benign laryngeal growths which at present is almost universally accepted is to the effect that no external operation should be performed unless an experienced laryngologist has unsuccessfully endeavoured to remove the growth *per vias naturales*. Broadly speaking, I think this principle to be a sound one and to hold good now as much as ever. At the same time, in the light of the experience gained within the last 30 years, it appears to me that one ought not to be too dogmatic, and that in an individual case the observer's own judgment ought not to be too blindly subordinated to generally accepted canons. Undoubtedly in the enormous majority of benign laryngeal growths a competent specialist will be able, particularly since the introduction of local anæsthesia by means of cocaine, to satisfactorily effect removal by intra-laryngeal operation. Still, there are exceptions to this rule. Thus, above all, cases of multiple papillomata in small children form a group the possession of which has by no means been ceded by the surgeon to the laryngologist. It is true that here again the intra-laryngeal method has made considerable progress within the last few years. Kirstein's method of direct laryngoscopy and Scanes Spicer's introduction of the combination of general anæsthesia by means of chloroform with local applications of cocaine to the pharynx, whereby the troublesome salivation which formerly was the greatest obstacle to the performance of intra-laryngeal operations under a general anæsthetic is prevented or, at any rate, greatly diminished, have greatly facilitated the performance of intra-laryngeal operations even in small children and in towns of sufficient size to support the existence of a laryngologist and in large hospitals in which every possible assistance and after-care are warranted even in the cases of small children attempts at intra-laryngeal removal of multiple papillomata nowadays ought to precede if possible external laryngeal operations. But unfortunately cases of this sort will occur where no favourable conditions for intra-laryngeal removal exist and the grave question arises, What is to be done under such circumstances? Personally I should be in favour of mere prophylactic tracheotomy being performed and of the child wearing its tube until it had grown up sufficiently to assist intelligently at subsequent efforts at intra-laryngeal removal of the growth. But a former colleague of mine at St. Thomas's Hospital has drawn my attention to a contingency of which, if I remember rightly, he had seen a sad real illustration. Cases of this sort unfortunately not rarely occur in children of poor parents who are compelled to leave their children to themselves whilst both father and mother are following their occupations. Supposing there were several children in a house one of whom, for the reason now under discussion, was wearing a tracheal cannula, and that during play or a childish quarrel its tube was torn out from its throat, speedy death from suffocation might supervene before help could be afforded. The possibility of such an occurrence ought not to be lightly dismissed from one's thoughts, and if it be present I would rather, though not cheerfully, agree to the performance of thyrotomy than leave the child for years under the shadow of an almost ever-present danger. Should thyrotomy be resorted to under such circumstances one ought not to flatter oneself with the idea that by gaining easier access to the growth with the performance of laryngotomy a greater guarantee against recurrence would be offered than by the employment of the intra-laryngeal method.

Cases abound in laryngeal literature in which thyrotomy has had to be performed over and over again in cases on multiple papillomata in children, and an experience of my own which strongly bears upon this question has shown me the utter futility of the belief that in cases of a tendency to papillomatous degeneration this tendency can be eradicated by external operation. This experience refers to a case which I have reported in the *Archiv für Laryngologie*, vol. vi., Heft 3. It was the case of a man, aged 64 years, in whom I performed thyrotomy with removal not only of the growth, but also of the healthy zone in its entire neighbourhood, on account of what was supposed to be an epithelioma at the time of the operation. The removal, needless to say, was much more thorough than one would ever aim at in a case of benign papilloma. Nevertheless, four years later, practically the whole larynx of this patient was in a condition of papillomatous degeneration. If such an event could occur after so radical an operation, how much more likely will the occurrence be after mere thyrotomy and removal of the innocent growth in a case in which thorough removal of the healthy neighbourhood can hardly be considered permissible. It would not, therefore, be with a light heart that I would ever agree to the performance of thyrotomy for multiple papillomata in children, and cases in which it ought to be performed will certainly be very scarce. I did, however, not wish dogmatically to exclude altogether the propriety of its performance under certain exceptional circumstances, such as mentioned before. Another exception to the general rule named at the beginning of this paragraph may occur in cases of exceptionally large mobile laryngeal growths which may become suddenly impacted in the glottis and cause death before relief can be afforded. Such a contingency will

[9] Loc. cit.

[10] La Thyrotomie dans la Tuberculose du Larynx, Annales de la Société Belge de Chirurgie, No. 7, 1898.

[11] Heymann's Handbuch der Laryngologie, vol. i., p. 1326.

no doubt be extremely rare, but, as I know from sad personal experience, it may become a grim reality. An isolated case of that sort will not, of course, supersede the general accumulated experience of so many years, but if a similar case should again come under my notice I should certainly not persevere as I did with my endeavours at intra-laryngeal removal, but should after one or two failures either perform prophylactic tracheotomy and then resume intra-laryngeal operations or, more probably, should at once perform thyrotomy and remove the growth from the external wound.

(*b*) Malignant growths.—The last indication of thyrotomy which I have to discuss I believe to be both the most frequent and the most important one—viz., its indication in the early stages of intrinsic malignant neoplasms of the larynx. I have already mentioned that the operation in cases of malignant disease had been totally discredited in 1818 by the statistical monograph of Paul Bruns. Three years ago I endeavoured to show [12] that the condemnation which Bruns at the time (1878) was fully justified in passing was due to the fact that the operation at that time was almost always undertaken at a stage when the disease was much too far advanced for this form of operation. But in spite of the fact that our diagnostic powers of the early stages of intrinsic cancer and sarcoma of the larynx have made enormous progress since those days, that the technique of the operation itself has been greatly improved, and that its results nowadays, in really suitable cases, are of the most encouraging nature, the operation, except in Great Britain, has not yet fully recovered from the universal prejudice raised against its performance 22 years ago. A few operators, such as Butlin, Chiari, Schmiegelow, and myself, have repeatedly of late years endeavoured to convince the profession of the enormous usefulness of thyrotomy in really suitable cases of malignant disease of the larynx. Unfortunately, however, our efforts have hitherto, as far as I can judge, been greatly interfered with (1) by recent statistics, which owing to their controversial compilation do not, I am convinced, represent the *real* achievements of modern thyrotomy, and (2) by the rivalry of the two methods which, as it were, form the opposite poles of possible surgical interference in the class of cases now under consideration—viz., the intra-laryngeal method and partial, or even total, extirpation of the larynx. I therefore warmly appreciate the selection of this subject for discussion at an international gathering of this character. It is quite true that not many arguments are likely to be advanced which have not already been made use of in recent papers on this question, and I personally shall refrain from reiterating at length my own views, partly on account of the limited time at my disposal and partly because I have said practically all that I could say in my various papers on the subject.[13] But a few facts seem to me to stand out so prominently, both from the results obtained by various methods and from the considerations which could be urged in favour or in disparagement of any of the rival methods of surgical interference now in use, that I wish in conclusion of my paper to lay them before you in as concise a form as possible.

We are all agreed, I take it, (1) that no internal medication of any kind has the least influence upon the course of malignant disease of the larynx, and (2) that surgical measures are the more likely to be permanently successful the sooner they are undertaken—i.e., at the time when the mischief is still purely local and not yet generalised. For the last-named purpose it is of the highest importance that the *early symptoms* of malignant disease of the larynx should be known *to every general practitioner*, and that the superstitions, unfortunately still too prevalent with regard to this question, should for ever be swept away. It ought to be generally known that the symptoms now usually associated in medical minds with cancer of the larynx—viz., cachexia, pain, swelling of the cervical glands, fœtor of the breath, and expectoration of blood—as a rule only occur in the *later* stages of the disease and may even be absent, one or several of them, till the very end of life. It ought to be generally known, on the other hand, that, just in those cases which give the very best chance and which are particularly suited for thyrotomy—i.e., in cases in which the disease begins on the vocal cords—the *only* objective initial symptom is usually hoarseness, and that if a person above the age of 50 years, particularly a man, has suffered for some length of time from some inexplicable dry hoarseness without any further symptoms his case ought to be considered suspicious enough to be subjected to laryngoscopic examination at the hands of an expert. When once these simple truths have become common property, malignant disease of the larynx will be much sooner recognised than, unfortunately, even now is the rule, and the proportion of lasting success from surgical interference in this terrible disease will become much greater than it is at present.

Now, if a suspicious growth be discovered in the larynx, a part should, if possible, be removed by intra-laryngeal operation and submitted to microscopical examination; should this, however, be impossible, or should the result of the microscopical examination be indecisive, the clinical observer must have the courage of his opinion and not wait too long until it is either too late altogether or until such drastic measures as partial or total extirpation of the larynx are the only means by which a cure can possibly be hoped for. Better, as I have said on a previous occasion, a thyrotomy performed where milder measures might possibly have sufficed than a life lost or a most serious and mutilating operation rendered necessary by waiting too long. I would therefore put it as a clear indication for thyrotomy that in all cases in which the presence of a malignant growth in the interior of the larynx, of a still circumscribed character, has either been definitely ascertained or has been rendered, at any rate, very probable from the clinical symptoms thyrotomy should be performed with a view to eradicating the disease by subsequent removal of the growth itself with a zone of surrounding healthy tissue. In those cases in which the disease is still limited and situated within the confines of the larynx proper, without the cervical lymphatic glands being as yet infiltrated, this simple operation will be found to suffice, not only for the radical extirpation of the disease, but also for the prevention of recurrences.

Without wishing to anticipate in any way the conclusions of my co-referee, Dr. Goris, I must state here, to justify my own attitude, that in my own private practice I have succeeded, by following these principles, in lastingly curing 83·3 per cent. of all the patients whom I have operated upon by thyrotomy. At the same time I wish again emphatically to repeat that such results can only be obtained by the selection of cases which are really suitable for this form of operation. Very advanced disease, infiltration of the cartilaginous framework itself, affection by contiguity of neighbouring parts such as the pharynx, tongue, or œsophagus, extensive infiltration of the cervical lymphatic glands, very old age, concomitant chronic and serious disease of the lungs or bronchial tubes may, of course, from various points of view, be so many contra-indications to thyrotomy in particular and to other external radical operations in general.

Every single case ought to be decided upon on its merits. No operator ought to start on his operation with the determination to perform only thyrotomy, and nothing else. If in the course of the operation the disease should be found to be more extensive than could have been judged by laryngoscopical examination the compass of the operation should either be changed into partial or even total extirpation of the larynx or the attempt at radical operation ought to be altogether abandoned. What I have particularly at heart is that thyrotomy should not again be discredited by being undertaken in *a priori* unsuitable or in much advanced cases. Its real sphere of usefulness lies in the early stages of true intrinsic cancer or sarcoma of the larynx. Personally I am convinced that intra-laryngeal surgery will never be able and, indeed, in its own self-understood interest ought not even to try, to rival thyrotomy in cases of malignant growths of the larynx.

The principle so universally acknowledged in surgery—viz., that operation for malignant disease can never be successful unless really radical—so much militates against the employment in this class of cases of intra-laryngeal operations, which, from the nature of things, do not afford

[12] Zur Frage der Radikaloperation bei bösartigen Kehlkopfneubildungen mit besonderer Berücksichtigung der Thyreotomie, Archiv für Laryngologie, vol. vi., Heft 3, 1897.

(This paper has been translated into French and published in the Supplement of No. 22 of the Revue de Laryngologie, Otologie, et Rhinologie, 1895.) 2. The paper already referred to in the Archiv für Laryngologie, 1897. 3. Die Thyreotomie bei bösartigen Kehlkopfneubildungen, Die Therapie der Gegenwart, April, 1899. 4. Einige Bemerkungen zu der neuen Sendziak'schen Statistik über die operative Behandlung des Larynxkrebses, Monatsschrift für Ohrenheilkunde, November, 1899.

a guarantee as to the thoroughness and completeness of the removal, that I honestly believe that, in the interest both of the operation and of the reputation of laryngology, in none but the most favourable cases should attempts be made to treat malignant disease of the larynx by endolaryngeal operation. I must frankly confess that even the reports of cases which have been successfully dealt with by intra-laryngeal operation have not been able to shake in the least my conviction going to that effect. The field is wide enough, in all conscience, for intra-laryngeal surgery without this very dangerous ground being contested.

On the other hand, there is ample scope for intra-laryngeal operations of the more extensive kind, such as partial or total extirpation of the larynx in cases in which the disease either has been *a priori* unsuitable for thyrotomy or in which the diagnosis has been arrived at too late for the minor operation to be undertaken with a reasonable chance of success. The results of Professor Gluck and others have shown us how much can be done by some operations in even apparently desperate cases, and I most heartily congratulate him and his followers on having by such operations saved life in an ever-increasing number of such advanced cases. But what I protest against is that these heroic measures should be undertaken in cases which do not really require them. There ought always to be some proportion between the degree of the disease and the operative measures undertaken to cure it, and from my literary studies on the subject I am seriously afraid that this principle has not been adhered to of late by every operator. Those who advocate thyrotomy in those early cases have been assured time after time that their endeavours were being followed with "sympathetic interest," but at the same time I regret to say that I have the impression as if their practical results were persistently ignored.

The time has now fully come when everybody should be capable of forming an opinion on this question, and if the results obtained be scrutinised with an unbiased mind I have no doubt that the chief indication for the employment of thyrotomy will in future be found in early intrinsic malignant disease of the larynx.

A NEW DISEASE WITH A SPECIFIC URINARY REACTION.[1]

BY N. F. SURVEYOR, M.D. BOMBAY, M.R.C.P. LOND.

ABOUT the early part of October, 1899, a young Parsee woman received rather a nasty cut on the tip of the thumb of the left hand. There was much bleeding at the time and the wound had not healed up even at the end of the month. About Oct. 29th she complained of smarting pain in the left eye. There was slight congestion of the conjunctiva, to relieve which simple warm astringent lotion was applied to it. On the next day the patient was much the same; during the night, however, the left side of the face was considerably swollen. In the morning when I saw her there was some redness of the part. The swelling, which was rather œdematous in character, seemed to start near the region of the left parotid gland and to extend over the cheek, nose, lips, and eyelids of the left eye. It did not extend to the right side. The inside of the mouth was also somewhat swollen and tender. The tongue and the gums were not involved. The swelling had very slight tendency to extend on the right side near the lips. There was increase of conjunctival congestion and there was much lacrymation. The skin over the left ear was not so much affected. The whole part was covered with small pin-head-like vesicular eruption. There was much smarting pain and a sensation of heat was complained of. There was no rise of temperature, nor did it rise higher than 99° F. during the whole course of the disease. The wound on the thumb was found to be dry and had an unhealthy look about it. There were present a few fine vesicles on both hands. There was no swelling of the left hand nor was there any pain except near the wound. On closer examination a thin bleb was found at the root of the left thumb on the following day. This was opened and serous fluid escaped which did not show any micro-organisms under the microscope. Thinking that erysipelas was threatening I painted the swelling with tinctura ferri perchloridi, tinctura iodini and Ferris's linimentum belladonnæ in equal parts. This caused some temporary smarting; however, the swelling and pain were decidedly less after a time. Internally the following prescription was given: three drachms of liquor hydrargyri perchloridi, 15 grains of potassii chlorati, 15 grains of potassii iodidi, 15 minims of tinctura nucis vomicæ, one and a half drachms of tinctura chloroformi composita, aquam to three ounces, misce—fiat mist., divide into three doses, one every four hours. 31-10-1899. On the next day—i.e., Nov. 1st—the condition was much the same. Hoping to obtain some information I examined the urine, which, however, showed nothing unusual as regards the ordinary constituents, except that it was rather watery and poor in urea, uric acid, indican, and salts. However, on adding a drop of strong caustic soda solution to the centrifugalised deposit, with a view to testing for pus, I found that the urine assumed a bright, pinkish purple colour. Examination of the urine which had been passed during the whole course of the illness showed the same reaction with varying intensity. There seemed slight periodicity; thus, about from one to two hours after a dose of the mixture it happened to be more marked. Again, lighter coloured urine as a rule gave feeble reaction. The colouring matter was generally completely brought down by the precipitated phosphates and the fluid became almost clear on centrifugalisation.

The precipitate was scarcely, if at all, soluble in any of the solvents that I tried. Thus distilled water, alcohol, ether, turpentine, chloroform, xylol, benzol, and carbon bi-sulphide remained perfectly clear even after repeated shaking for days together. Glycerine seemed to take it up very slightly. The reaction could be obtained by adding any other alkali, thus caustic potash, ammonia, liquor calcis, chlorinated lime, and dilute hypobromite of soda produced the same reaction; excess of the last-mentioned, however, destroyed the pigment. Even strong acids destroyed the pigment-producing substance very slowly, and on alkalinising the urine the reaction was obtained after more than five months. Thus the addition of hydrochloric acid to the extent of making a 20 per cent. solution was not able to destroy the substance after 181 days. In this case it was noticed that the supernatant fluid gave the reaction very feebly, while the scanty brownish deposit produced the reaction readily. In another sample the reaction was scarcely perceptible after four months—in this case, however, I had no opportunity of testing the deposit. Heat did not destroy the reaction. The pigment under the microscope appeared to be made up of amorphous granules. The spectroscope did not show any absorption band. At the suggestion of Dr. Meyer, experiments with oxidising agents, like permanganate of potash and hydrogen peroxide, and with deoxidising substances, like stannous chloride, Stokes's fluid, sulphide of ammonium, yellow sulphide of ammonium, and ferrous sulphate, showed that the colour became faint in the presence of deoxidisers, while oxidation with hydrogen peroxide seemed to make the colour brighter at first, then it gradually became faint, but total destruction of the colour was not produced even after five months. Yellow sulphide of ammonium turned the solution yellowish; however, on the addition of hydrogen peroxide, feeble reaction was reproduced. The effect of ferrous sulphate, Stokes's fluid, and permanganate of potash was disguised by the coloured oxides that were precipitated, while the ammonia, present in sulphide of ammonium, interfered with the effect being well observed. Stannous chloride and hydrogen peroxide were the two chemicals which I found best suited for studying the effect. At the suggestion of Dr. Herbert I tried the effect of solution of iodine in potassium iodide. The colour of iodine masked the reaction and the deposit became whitish in character; in fact, this reagent acted as a deoxidiser; however, on neutralising the iodine with excess of caustic soda feeble reaction appeared, and on oxidation with hydrogen peroxide the intense reaction was at once produced. The observations for the presence of this reaction were continued till Nov. 17th, on which day a negative result was obtained.

On the night of Dec. 5th, 1899, the attack recurred. On the previous day there had been some pain in the left ear. This time the eye was less affected while the pain in the ear and

[1] A paper read before the Bombay Medical and Physical Society.

the swelling of the skin near it were more marked. On this occasion the swelling and pain were not so severe as during the first attack. This time the whole course was febrile like the first one. In other respects there was no difference noticed. This time there was no external wound on any part of the body, the thumb having quite healed up. Before any internal medicine was given I had an opportunity of examining the urine and the same reaction was obtained. On this occasion there was a slight trace of albumin and it was found that saturating with neutral ammonium sulphate produced a dirty grey amorphous deposit. This was filtered, and the filtrate gave the reaction rather feebly, while the precipitate, although washed repeatedly with saturated neutral ammonium sulphate solution, gave the reaction strongly. However, on washing another sample with distilled water the reaction-producing substance was removed from the precipitate.

Here I may state that the presence of this substance is likely to mislead one as regards the presence of peptone. Fehling's solution produces a beautiful pale rosy colour identical with that of peptone reaction. The absence of peptone in this case was proved by the salicyl sulphonic acid and neutral ammonium sulphate test, while a control test with peptone added to urine failed to give the purple reaction with an alkali.

Now, finally, I have to say a few words regarding the nature of this substance. One thing is certain, that this reaction is not found in any other sample of urine which I have examined. However, I have reason to believe that the substance from which this pigment is produced does exist in a modified form in the urine in certain cases. In the sample of urine treated with hydrochloric acid mentioned above I have said that I was able to obtain the reaction by adding caustic soda. However, in my first experiment, there being probably too much brown deposit used, I found that the alkaline solution was brownish in colour, so I added a little hydrogen peroxide with a view to see if the brownish pigment could be so altered as to reproduce the pink reaction. This surmise was at once verified, and since then I have tried the same test with two other samples in which the pigment was not present in fresh urine and the brownish deposit had assumed a pale rosy colour similar to that which is produced by leaving the purple deposit in contact with hydrogen peroxide for a long time. This was in a case of scurvy and the other one was in a case of fever brought on by slight hepatic congestion. In other cases I have not obtained this modified reaction, and it is interesting to note that the urine of the patient whose case gave this reaction gives neither the original nor the modified one now that she has quite recovered.

I may state here that the patient is a martyr to asthma; yet during a rather severe fit I have failed to obtain the reaction with her urine. In the mixture given for this illness will be found tinctura chloroformi composita. Now this contains carmine as a colouring agent; so my attention was directed to prove whether or not this reaction was due to some special idiosyncrasy on the part of the patient to excrete this substance. Experiments on other people failed to give the reaction. Every single drug was tried separately and collectively on myself with negative result. On the other hand carmine was added in minute amount to healthy urine and the reaction was at once obtained; however, this reaction is soon destroyed by hydrogen peroxide. To be sure that carmine had nothing to do with the urinary reaction I availed myself of the opportunity afforded by the second attack, when the drug was withheld, yet there was no difference in the reaction produced. The blood was examined for the reaction during the second attack with negative result. At the suggestion of Dr. Lyons I tried Bremer's test with Congo-red, methylene-blue, methylene-blue and eosin fuchsin, and erythrosin. There was no difference noted in the staining reaction except in the case of Congo-red. This stained the blood film more deeply than in a control case, quite the reverse of that which happens in diabetic blood. I have not had an opportunity of verifying this observation under more rigid conditions, so I cannot say whether or not there is a specific staining reaction present in this disease. The filtered pigment being allowed to dry in air becomes bluish in colour. As regards the nature of this disease I abstain from making any observations now. In conclusion, I have to state that from a record of 195 cases of urine analysis I have not seen a single case giving this reaction.

Bombay.

ECZEMA AND THE ALLIED DISEASES: AN OUTLINE OF THEIR ETIOLOGY, PATHOLOGY, AND TREATMENT.[1]

BY W. T. FREEMAN, M.D. DURH., F.R.C.S. ENG.,
SURGEON IN CHARGE OF THE SKIN DEPARTMENT AT THE READING DISPENSARY.

I HAVE been asked to open a discussion on eczema and the allied diseases with the hope that a large number of members will express their opinions regarding the etiology, pathology, and treatment of this widely-known and interesting group of disorders.

First of all, how are we to define eczema? On this very subject at the Edinburgh meeting of the British Medical Association in 1898 an eminent dermatologist, quoting John Hunter, said "that definitions were the most damnable things," and they are so. I would define eczema as "a serous inflammation of the skin not produced by any form of external irritants." At some stage or other of its evolution there is or has been exudation of serum. In the acute stage, at all events, the clinical signs of inflammation—heat, pain, redness, and swelling—are all present, but the rise of body temperature that accompanies other forms of inflammation is almost invariably absent. I agree with those authorities who regard an erythematous, a papular, a vesicular, a pustular, a dry or a scaly eczema, as simply stages of the same complaint. I would recognise as the great sub-variety of eczema "eczema seborrhoicum," and one means by that an eczema occurring in a patient who also suffers from seborrhœa, and it usually commences and spreads after the same fashion as seborrhœa, starting on the scalp and progressing slowly downwards over the body and limbs. Sweat eczema, follicular eczema, or sun eczema barely deserve the name of sub-varieties, and eczema marginatum is body ringworm attacking sweaty parts of the skin.

That there is real difficulty and confusion in connexion with the terminology of this disease is very easily exemplified, for do we not often hear people talk of the secondary eczema produced by the irritation of the itch parasite? Now this does not fit in with my definition of the complaint nor with any of the terminology usually accepted by dermatologists. Scabies, in fact, is produced by a direct irritant to the skin, and the various skin conditions associated with it should be varieties of dermatitis. If we are to retain the old familiar term—and it would certainly take a lot of knocking out—we should at all events have a clear image in our minds of what we mean by eczema and what we mean by dermatitis. We all appreciate one great difference between a dermatitis and eczema. The former is under control—i.e., the irritant can under ordinary circumstances be removed; but it is not so with the latter disease, only too frequently does it baffle us and get out of control.

THE ETIOLOGY OF ECZEMA.

Personally I prefer to consider eczema as a distinct disease, as an entity as clearly defined from other diseases as is, for instance, enteric fever from pneumonia. Hereby I commit myself to the parasitic theory, believing that it is brought about by the behaviour of a specific organism, possibly the "morococcus" of Unna, just as the other compared diseases are brought about by the doings of the bacillus of typhoid fever or the pneumococcus of inflammation of the lung. When we speak of eczema being produced, as it very often is, by a chill, or through nervous influence, or by a gouty inheritance, or by diabetes, we do not mean that these conditions are the actual cause of it. We mean that they are the exciting causes, that they reduce the soil suddenly, or perhaps quietly, to a condition favourably receptive to the eczema "morococcus." A chill may equally be the exciting cause of eczema, pneumonia, scarlet fever, or rheumatic fever, or of any other complaint, and the public at all events are quite satisfied with this sole explanation. Even to us, knowing more of the specific cause in each case, there is still a veiled pathological dreamland; for why should a chill in one instance favour the attack of the eczema organism, and

[1] A paper read before the Pathological Society of Reading on June 14th, 1900.

in another that of the pneumococcus, and in another that of the tubercle bacillus? Well, there is the individual to be considered; the altered conditions produced by the chill in the one case may be very different to the conditions brought about by it in the other. Then comes, too, the question of the "survival of the fittest"—I mean of the fittest organism. One particular set of bacilli in the neighbourhood of the depressed patient may be infinitely more numerous, or, again, one bacillus may be healthy and fit for attack while another may itself be suffering from a chill of some kind or be knocked out at the time from the attack of a better conditioned organism. We must not confuse the attentions of the staphylococcus pyogenes aureus or albus with those of a specific organism. Their doings are accidental and preventable.

In the January and February numbers for 1899 of the *Dermatological Journal* Dr. Leslie Roberts has a most excellent and exhaustive article dealing with the pathology of eczema. He opens it by drawing attention to the inflammatory, secretory, excretory, and digestive functions of the epithelium of the skin, or rather of the cellular components of the epithelial layer. To think of special skin cells possessing an inflammatory function is only funny upon first consideration, for, after all, they are strictly comparable to the cells of the epithelial layer along the alimentary and other tracts. There is no doubt, so far as our present knowledge goes, that only individual sets of cells along the mucous tracts do individual business, and it is fair analogy to give separate functions to separate skin cellular tracts. As to the digestive functions of the skin Dr. Roberts clearly proves them by actual test-tube reactions carefully watched in an incubator. But in the more practical part of his paper he allows no sharp line to be drawn between dermatitis and eczema. There are three main propositions that I would ask the members of this society to express their opinions upon. 1. Is eczema an entity—a specific disease? 2. Is it due to the fact that certain functional epithelial cells are excited into over-activity by some kind of irritant? 3. Is there any distinction at all to be drawn between eczema and dermatitis?

I will now cite just a few practical examples of the difficulty of the question. At a meeting of the Dermatological Society of London on March 14th I examined a patient brought forward as a case of "pyodermia." At a meeting of the British Dermatological Society on Feb. 23th I examined some pure cultivations of the staphylococcus aureus from a case of "acute recurring eczema." Then, again, there are the cases of exfoliative dermatitis which nowadays we frequently see, and which no doubt we saw quite as frequently in the days gone by, but we simply did not bother to differentiate and called them all "eczema." The sceptic will say that it did not matter—the patients did just as well and what particular coccus was knocking about was quite immaterial. This, however, is not true, for without a true pathological and bacteriological idea of what is going on it is quite impossible to methodically treat any case of skin disease—or for the matter of that any kind of disease whatever.

Some of the conditions simulating eczema are not easy of diagnosis. To compare dry eczema with psoriasis, for instance, or seborrhœic dermatitis with psoriasis, or eczema with seborrhœic dermatitis, we must often simply depend upon the general picture as shown to us. The scales of seborrhœic disease are more or less oily and there is not the red dry surface left as after the removal of the scales of psoriasis or the greater or lesser attempt at exudation as noted in the case of the cleansed eczema patch. Dermatitis herpetiformis is often not recognised by the general physician, but it is very important that it should be. Here again the general picture, and particularly the grouping of the vesicles and bullæ, will generally settle the question. The early stage, the pre-mycosic stage of granuloma fungoides, should be recognised. Not long ago at a meeting of one of the dermatological societies at which I was present a case was brought forward in a man as pityriasis rubra. It was recognised by Dr. H. R. Crocker and by others who were present as an early case of mycosis fungoides. There were, however, no signs of tumours present. They developed nevertheless within six months and within twelve months the patient was dead. Indeed, the disease is so invariably fatal that only the worst prognosis can be given. This man as he was shown for the first time corresponded with *les hommes rouges* of the French school. These cases also appear in their early stage pretty often as obstinate general cases of acute or subacute eczema, or, if you wish to call them so, as cases of acute or subacute general dermatitis. Indeed, a very obstinate general eczema should be regarded with grave suspicion. Having once seen one or two cases of developed granuloma fungoides one would not be likely to miss even a single very small tumour. It is useless to remove these tumours.

Patches of eczema and lupus may be very difficult to distinguish the one from the other. I can think now of a man being shown at the Dermatological Society a year or two ago with patches on his hands. They were on the back of the hand, were abruptly circumscribed, were covered with a slight crust, and were thickened. They looked very much like patches of lupus, but I believe that they subsequently turned out to be patches of eczema. There was much difference of opinion upon the condition as then shown. The abrupt margins, the thickening, and the slight crusts made them look very much like lupus. Such cases would have to be watched. If the patches spread by their edges steadily advancing and if some amount of scarring were left behind, the diagnosis would be for lupus, and a tuberculous history might still further assist this diagnosis. But if they spread more diffusely and an improvement was brought about by treatment and without any scarring being left behind then such patches could be definitely fixed as those of a chronic eczema.

The subject of seborrhœa and its allied conditions was brought forward at a discussion at which I was present only last month. Mr. W. Anderson, Dr. Stephen Mackenzie, Dr. H. R. Crocker, and others took part in the discussion. To enter into the details would take too long a time, but the close connexion or relationship between pityriasis of the scalp and seborrhœa sicca et oleosa, and seborrhœic dermatitis and alopecia, was clearly brought out. It seemed to be generally agreed that the waxy and oily forms of seborrhœa were the same disease either in different stages or on different soils. The dry scalp pityriasis is possibly a condition by itself. Seborrhœic dermatitis, or eczema seborrhoicum, is probably seborrhœa complicated by the invasion of the staphylococcus pyogenes aureus et albus. All of these conditions lead to baldness of the scalp or of any other part of the body, and it will be remembered that Sabouraud has lately demonstrated a cocoon of micro-bacilli and epithelium which belongs to, and is the destroying agent of, alopecia areata and which is also, he says, the actual cause of seborrhœa. He also says that these micro-bacilli pave the way for the various pus organisms which so frequently complicate these conditions. Just in passing I would say that there is no doubt that some forms of alopecia of the scalp are produced by the microsporon or by the endo-ectothrix fungus of ringworm.

There are one or two other forms of disease allied to eczema to which I ought to allude. They are amongst those produced by pus cocci. I think we may at once brush aside "ecthyma" as merely being an obsolete name for a form of pustular eczema or for impetigo contagiosa attacking such parts as the legs. Impetigo contagiosa we must accept as a separate entity. We are all familiar with the crusty patches of this disease, which appear, indeed, to be simply dabbed on the surface, and which, unless irritated, have no surrounding erythema and leave no after scarring. Then there is that particular form of sycosis produced by the staphylococcus pyogenes. I am speaking, of course, only of the simple form of folliculitis known as sycosis and not of the hyphogenic sycosis. It is said that it is more painful and difficult to epilate in the coccogenic than in the hyphogenic form, but the true test is the microscope.

I heard it laid down as an axiom the other day by Dr. Radcliffe Crocker that we should not use the terms "impetigo" or "impetiginous eczema" unless we are referring to impetigo contagiosa. Any authoritative statement of this kind is useful as tending to prevent loose descriptions and definitions. Then what do we mean by "prurigo"? I think it is a separate disease. The history almost always dates from infancy, the earlier manifestations being, perhaps, those of lichen urticatus. It attacks by preference the extensor surfaces and the leading symptoms are the hard, dry papules often topped by a crust of blood the result of scratching. There is something about the scratches which is difficult to describe but which is yet almost pathognomonic. The disease lasts indefinitely; the symptoms admit of amelioration but the condition is not, strictly speaking, curable. I saw an uncommon case of prurigo in a boy the other day in which the face and hands were alone affected.

All the varieties of erythema might be considered allied

diseases of eczema, as also dermatitis due to pediculi or to the acarus of scabies, or to the handling of the primula obconica; also here in Reading we should not forget the skin irritation caused by the handling of hyacinth bulbs. I have dealt with this subject in the number of the *British Journal of Dermatology* for February, 1897. I content myself with drawing attention to these additional diseases and conditions as possible subjects for discussion.

It has been suggested to me that acne in its varieties, and boils, and carbuncles were diseases allied to eczema. Pustular eczema, impetigo contagiosa, boils, and carbuncles are, at all events, due to the same cause. There are plenty of explanations as to why we should find pustular eczema in one patient, a suppurative folliculitis in another, and acne, boils, or carbuncles in another. The reasons for these various manifestations, if they are due to one actual cause, might form a part of the discussion. In connexion with all these pustular forms of skin diseases I think we may be apt to forget that pus may exist without the presence of pus cocci.

THE TREATMENT OF ECZEMA.

With regard to the treatment of eczema one of our members said to me only the other day that he treated his skin patients with zinc ointment and left the rest to Providence. It is an easy method of disposing of them, but I am sure it will be better for the patients if they are carefully and systematically treated. The physician in ordinary can say much to his patients without any fear of contradiction, but patients suffering from skin disease can see and note progress for themselves.

The first great principles in the treatment of eczema and its allied diseases are to soothe when the conditions are acute and to carefully stimulate the skin into healthy action as inflammation and irritation subsides. In a diffuse eczema one of the most important soothing elements is rest; oftentimes absolute rest is required.

Where there are a lot of dirt and crusts about all should be removed before any special form of treatment be adopted. Thorough soaking in weak carbolic oil is one of the best methods of loosening crusts, whether upon the head or elsewhere. The most careful and explicit directions must be given as to the removal of crusts from the scalp. There are various other substances that may be used for the removal of crusts, for instance, boric starch poultices, solutions of bicarbonate of soda or borax, or fitting the head or limb with an impermeable covering. Having removed all crusts and dirt as far as possible the next thing is to soothe and disinfect. There is hardly a skin disease which during some portion of its career does not require anti-parasitic treatment, and the application requires a great amount of care. It would not do to rush away with the idea that sulphur ointment would always do as the disinfectant. If my good friend aforesaid ever should go outside his zinc ointment treatment for acute eczema and the like diseases I think he would apply sulphur ointment, with the result, perhaps, that he would produce a dermatitis. Not that I am laughing at sulphur, for carefully applied in strengths suitable to each case it is an invaluable remedy. Mercury, ichthyol, tar, resorcin, and similar parasiticide remedies suit still better, some in one case, some in another. Experience gradually teaches us when to order lotions or sprays and when ointments or pastes. In any case the remedy must be kept at work. It is not a bit of good simply perfunctorily to tell the patient to dab on this or that ointment or lotion; he must be told how to apply it and how often to apply it.

It would be interesting to hear what members think with regard to the washing of eczema patients. I think that the patients should be washed from time to time for the better disinfecting of the parts, but I should in all cases order soft water or softened water and careful drying afterwards, and the general directions given for the cleansing of the patient should be similar to those that would be given for the cleansing of a wound. Lassar is one of the strongest advocates for these periodic washings, but many dermatologists are much against water being used to the skin in eczematous conditions. This is a fair question for discussion. Lassar particularly recommends tar-baths.

There is one caution about washes and sprays that everyone might not think of, and that is if the skin is broken do not order spirituous sprays or washes. Ordinary frequent washings in eczema and dermatitis are not to be allowed. The cleansing and disinfecting of the parts is the point. For macular and erythematous eczema, and also for some forms of weeping eczema, personally I think very highly of dusting powders. French chalk, cimolite, and powdered talc all make useful dusting powders. Oxide of zinc or starch powder is good for astringing or stiffening purposes, and salicylic acid, boric acid, or sulphur may be added for disinfecting purposes. I have used muslin bags filled with powder, as suggested by Unna, with excellent effect in situations like the groin.

Dry patches of chronic eczema, either hypertrophic or atrophic, are amongst the most troublesome conditions to cure; so, too, are those hypertrophic patches of lichen planus that one so frequently meets with. Stimulation, often strong stimulation, is necessary, but the results must be watched. It seems to me that what suits one case does not suit another and it is often necessary to ring the changes. Strong mercurial or chrysarobin ointments may be useful, tar in some form, or a salicylic and creasote paste, or they may be painted with 10 per cent. to 20 per cent. solutions of caustic potash or nitrate of silver. Blistering is also a valuable means of starting a cure. Of these and of the many other remedies the secret of success with all of them is to keep them at work. Of course, this does not apply to blistering or to the application of strong caustic solutions. Probably some members will give their experience of the gelatin preparations and other varnishes and pastes now so largely used. I am very fond of a medicated plaster in some cases of chronic eczema; I think their great drawback is the fact that they are probably not recently made.

I have said nothing about baths, but having shown myself on the favourable side for the cleansing of eczematous surfaces I have practically committed myself to baths and I fancy there are but few who would not sometimes order baths in skin diseases. Baths of soda and borax, and glutinous, starch, and bran baths we must frequently order; of the rest sulphur and tar baths are perhaps the best. I think the value of baths and their methods of application would be an excellent point in connexion with treatment for discussion.

With regard to the general treatment of eczema and the allied diseases I attach less value to this than to the local treatment. Nevertheless, in conjunction with local applications it must often be of service. In acute disease—especially in plethoric and gouty subjects—undoubtedly free purgation and the use of drugs that will lessen vaso-motor resistance and produce a free action of the skin, kidneys, and mucous tracts generally will be of service. In diabetic skins, whether the condition be xanthoma or ordinary eczematous irritation or dermatitis, undoubtedly general treatment must be gone into. Also where there is evidence of trophic disturbance the nerve change or nerve instability has to be corrected if it be possible to do so. Neurosis is given great importance to by some dermatologists, and sedatives, such as the bromides, and stimulants or restoratives, such as the zinc salts or arsenic or strychnine, should be serviceable. Personally, I think that when we have to deal with such a class of drugs for the cure that we are getting into troubled waters.

Diet in some cases is of importance, but I think time would hardly permit the discussion of the dietary treatment. It is practically treating acute or chronic indigestion. With regard to the treatment at health resorts, and particularly at bathing places and spas generally, no doubt many patients will be benefited by visits to Harrogate, Buxton, Strathpeffer, Aix-les-Bains, Carlsbad, Homburg, and the like places, but it is usually, I think, the patient's general condition rather than the particular form of skin disease that suggests the particular resort. The seaside is not generally suitable for acute or irritable skin disease, but such a statement requires modification.

I do not know why, but it seems to me that medical men as a rule do not trouble themselves much about skin diseases; indeed, they are either to be cured with a dose of white mixture and some zinc ointment or there is nothing to be done for them, and yet I would venture to say that the skin with all its glands and appendages and cells is as beautiful and intricate an organ as any we have to deal with. Its duties in the life-history of the individual are manifold and wonderful to think upon. The physiology of the corium and epidermis and of the appendages which strike down into the subcutaneous tissues teaches us more than a little of the way we live and move and have our being. Its pathology is equally instructive and beautiful; bacteriology probably plays a more important part for it than it does for any other class

of disease. Without this knowledge how can we successfully apply our treatment? Yet how few of us take the trouble to master it and what is the result? If we choose to neglect what is really a beautiful and sightly organ when it is sound the patient with an unsound skin tries to get it cured elsewhere. He dodges here and there, tries first one quack nostrum and then another, usually goes from bad to worse from want of systematic guidance, and occasionally stumbles upon a right remedy at the right time and finds himself better or cured. Forthwith he curses the whole priesthood of medicine and extols the quack nostrum to the skies and the quack proprietor shouts it beyond such trivial confines and space will not hold his jubilations. Of the 101 not cured one hears nothing, even less than nothing, if they return for help to the proper channels. Here some of them will find a kindly and sympathetic practitioner who will take the necessary systematic trouble to alleviate and cure them. However, he is not the man to holloa and the patient soon forgets that he has been ill.

I feel that I ought to apologise for trespassing so much on this one line of argument, but I do it because I feel that if we are to beat down quackery and quack nostrums it is to be done by stronger personal efforts on our part to face troublesome and nasty cases instead of just throwing them over as nuisances. All this applies with more force to the difficulties of dermatology than to any other groups of disease. I believe that the profession is really more in the dark about the knowledge of and the treatment of skin diseases than of any other disorders, perhaps because we have thought that we saw everything and that to know about it and treat it was so very easy. We saw when we had failed and desisted in disgust; the physician in ordinary seldom knows when he has failed and plods on merrily with his patient perhaps as happy as himself. Hard workers are lifting the veil that has prevented the medical man from always producing good results in eczema and the allied diseases, and I will end by quoting an old negro proverb that has just come into my head—"It takes heaps o' licks to dribe a nail in de dark."

A CASE OF PUERPERAL SEPTICÆMIA TREATED BY ANTI-STREPTOCOCCIC SERUM, AND COMPLICATED BY PHLEGMASIA; RECOVERY.

BY A. HAMILTON WOOD, M.D., CH.B. EDIN.

THE patient whose illness I am about to discuss was confined on the afternoon of May 5th. The first stage was a long and tedious one, due mainly to extreme rigidity of the perineum. There was a superficial tear which, though very slight, may undoubtedly have been the source through which septic matter gained entrance into the system, seeing that the house and its occupants were by no means clean. I visited the patient on the following day and found her perfectly comfortable. She had little or no after-pains. I saw her again on the next day and found her much the same as before; the temperature was normal but the pulse was a little rapid. I was then rather afraid of some septic mischief setting in, and on calling on the following day, which was the third day after her confinement, I found her temperature to be 101° F. and her pulse 120. I gave her then five-grain doses of quinine with some hydrobromic acid to prevent as far as possible the uncomfortable head symptoms which are so apt to follow the continued use of this drug; also 15-minim doses of digitalis. She had some castor oil which moved the bowels well but had no effect on the temperature. I sent for one of the district nurses who douched her night and morning with 1 in 1000 corrosive (intra-uterine). The next day the temperature ran up to 104° and on the same night it was 105·6°. She complained of no pain and told me that she felt "all right but for a slight headache and a dreadful thirst." She was very sleepy and her expression was not anxious but rather drowsy and apathetic. The uterus, though enlarged and contracting badly, was not very tender, but there was a copious foul discharge, a lot of shreddy material returning each time with the douche. On this day, the fourth after confinement, I injected 10 cubic centimetres of anti-streptococcic serum, ordered her a little brandy every three hours, milk and soda-water, bovril, &c., and when I called the next day I found that the temperature had fallen from 105·6° to 102·6°. On that evening the temperature was about the same, 102·8°, so I did not inject any more serum. On the following morning it had fallen still further to 101·6°, but rose again in the evening to 104·2°. This was on May 11th, the sixth day after confinement. In the evening I again injected 10 cubic centimetres of the serum, the chart showing a fall on the next morning to 101°, but in the evening it again rose to 104·2°. Our supply of serum having unfortunately come to an end I could not inject any on that day. On May 13th the temperature in the morning was 100·4° and in the evening 104°, so I again injected 10 cubic centimetres of the serum. On the next day—that was about a week after the onset—the temperature fell to 100·6°; in the evening it was 101°. I now stopped the serum injections but continued the quinine and intra-uterine douching. The pulse, which up to now had varied with the temperature, had also fallen and was steadying down. I may mention *en passant* that from the commencement the secretion of milk was entirely arrested. On the 15th the temperature was 100·6° in the morning and 102° in the evening, but as the pulse was steady I did not mind the slight rise. On the next day it was a little above 100° and the patient was feeling a great deal better. The temperature fell still further on the following day and on the 18th it was down to normal, the pulse-rate falling simultaneously. The discharge, which for the last five or six days had been gradually diminishing, was now very slight. On the next day, however, the patient complained of a little pain down the back of the left leg, and on examining it I found the leg slightly swollen and tender, more especially posteriorly. There was not much tenderness above the popliteal space. The temperature ran up to 99·6° and the pulse to 86. For two days before this phlebitis set in; the bowels had not been opened. The patient had taken some castor oil, but had failed to get relief till an enema was given. I swathed the leg in cotton-wool and raised the foot of the bed. The quinine and digitalis were continued with the addition of some morphia to allay the pain. For the next two days the temperature remained at about 100° and on the following day she complained of pain in her right leg; this was only slightly swollen and not so tender as the left. The leg was wrapped in cotton-wool and bandaged as before. It is interesting to note that the left leg, as is invariably the case, was the first to be attacked and the severer of the two. On the following day the temperature fell to normal and remained so, except for a slight rise one evening due possibly to constipation. Towards the end of the month all pain had left the legs and by a little gentle massage the remaining swelling quickly disappeared. Since June 1st the patient has been getting up for a little each day, and at the time of writing (June 4th) she says that she feels herself again.

This case is deserving of some note, more especially with regard to the mode of treatment adopted. On the sixth day after the commencement of the disease, during which time three injections of serum had been given, the temperature fell considerably and remained down. But the question arises, would the same state of affairs have resulted from the administration of the quinine and digitalis alone without the anti-streptococcic injections? I think not. The intra-uterine douching, no doubt, played an important part in the treatment of the case, but apart from this I am of opinion that the success of the case was to a great extent due to the use of the anti-streptococcic serum. With regard to the after-effects, let me remark, the patient had absolutely no discomfort. Some hold that the serum produces a depressant action on the heart. It may be that three doses of 10 cubic centimetres each is not sufficient to cause any depression; all I can say is that in this case there was no depression, nor were there any uncomfortable symptoms whatever, either after each dose or after the third had been given.

Then a word or two with regard to the phlegmasia. It started in the left leg and a few days afterwards the right was affected, but to a less degree than the left. For a day or two previously she had been very constipated. This may be a mere coincidence, but it seems to support the theory that the rectum, lying as it does on the left side, has something to do with the phlebitis invariably starting on that side. This case, as well as others already published, may aid in inciting the profession to the further use of

anti-streptococcic serum in such cases as the above, my opinion being that it is undoubtedly worthy of a fair trial.

Falkland, Fife.

THE SYMPATHETIC ORIGIN OF POST-ENTERIC TACHYCARDIA.

BY P. CLENNELL FENWICK, M.B., L.R.C.P. LOND., M.R.C.S. ENG.,

SURGEON-CAPTAIN, NEW ZEALAND MOUNTED INFANTRY; LATE SURGEON TO THE CHRISTCHURCH HOSPITAL, NEW ZEALAND.

DR. C. BURLAND in his paper on Tachycardia following Enteric Fever[1] seen in military convalescents mentions a theory suggested by myself of a sympathetic origin of the cardiac phenomena. Having had the pleasure of assisting Dr. Burland in his investigation of the pulse-rate in typhoid fever convalescence I can fully endorse all his remarks. The actual percentages given by him were, if anything, larger than those stated in his paper, but he is no doubt anxious to keep well within the limits. The patients were most carefully examined and some of the more interesting were auscultated daily and the rapidity of the pulse was constant in all. It is a striking point that the only two cases in which the pulse was normal were those of a seaman and of a soldier who had escaped the hardships of the campaign by being stationed on garrison duty. Of the effects of the long marches and scanty food I can speak feelingly. My troop of the New Zealand Mounted Infantry left the base in splendid health. Every man had twice passed a severe medical examination and each had been selected from a large number of applicants. At the end of 700 miles marching a huge proportion had passed through hospital or were at that time on the sick-list. Cases of absolute exhaustion at the day's end were very common and cardiac trouble was a constant complaint at sick parade. Considering that these men had been selected on account of their splendid physique and excellent medical history it must be conceded that Dr. Burland's theory of overworked hearts has solid grounds of foundation.

Whilst discussing with Dr. Burland the reasons of the rapid pulse-rate which we so constantly found I recalled the many cases seen in New Zealand of irritable hearts due to thyroid overgrowth and remembering a proposal to treat this condition by excising the middle cervical ganglion I suggested to Dr. Burland that the cardiac irritability noticed by him in his convalescents from enteric fever might be due to a sympathetic disturbance arising in the superior mesenteric plexus and thence transmitted to the cardiac ganglia and plexus. The superior mesenteric plexus which supplies that portion of the intestinal canal chiefly attacked by the typhoid poison is so closely connected to the cardiac plexus that I saw no absurdity in suggesting that the intestinal inflammation might set up an irritation wave in the terminal filaments of the local nerve-supply which was transmitted or reflected to the ganglia or centre controlling the heart's action (exactly as the pain in hip-joint disease is transferred to the knee-joint) and thus react on a cardiac musculature already weakened and irritable from long-continued strain and insufficient nourishment and produce the rapid pulse noted by Dr. Burland.

The liquid evacuations in enteric fever surely point to a vaso-motor disturbance in the intestinal sympathetic supply, and if the typhoid poison can evoke one function of the nervous system cannot another reaction also take place? The liquid diarrhœa so often seen in nervous people, particularly in medical students undergoing the horrors of an examination, is an example of a vaso-motor explosion. Dr. Burland, whilst courteously declining my suggestion, advanced as an unanswerable argument that if typhoid inflammation could cause a nervous reaction then the same phenomena should also be seen in dysentery. My reply was that in typhoid fever the inflamed area was much larger and that the nerve-supply of this locality was in much closer connexion with the cardiac plexus than that of the rectum. The sympathetic supply of the latter is derived from the pelvic plexus which is directly joined by branches of the second, third, and fourth sacral nerves, and we may justifiably expect to find an irritation wave from the rectal sympathetic nerves reflected through its nearest nerve connexions; and surely the painful tenesmus so constant in dysentery is caused by reflection through the sacral nerves to the inferior hæmorrhoidal branches of the pudic nerves which is derived from the third and fourth sacral nerves and thus places the nerve-supply of the external sphincter in direct nervous connexion with the mucous membrane of the rectum. The marked nervous phenomena seen in the strangulation of a small piece of the intestinal wall, as in Littré's hernia, is surely an argument in favour of sympathetic irritation from the intestinal nerves being reflected to the gastric nerves or the vomiting centre.

A symptom seldom noticed in acute dysentery is a very painful throbbing pain in the lumbar region. This I can only account for on the supposition that the renal plexus is reflexly irritated from the nerves of the rectum. I have only seen this symptom in cases of severe dysentery, and tenesmus was also acute.

Having been for many months exiled from all medical literature I must apologise if my remarks show painful ignorance of current ideas.

[1] THE LANCET, July 28th, 1900, p. 253.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

CHARING-CROSS HOSPITAL.

A CASE OF FOREIGN BODY (CLINICAL THERMOMETER) IN THE BLADDER; LITHOTRITY; RECOVERY.

(Under the care of Mr. JOHN H. MORGAN.)

FOREIGN bodies are much more commonly found in the female than in the male urethra and this is doubtlessly due in part to the larger lumen and the shorter length of the female urethra and partly also to the more frequent occurrence of hysteria in women. If a skiagram had been taken it would probably have revealed the nature of the nucleus of the stone, for both glass and mercury are very opaque to the x rays. The only case which is at all parallel to the very interesting one recorded below is to be found in the *Medical Press and Circular*, 1894, vol. i., p. 546.

An unmarried woman, aged 32 years, was admitted into Charing-cross Hospital on May 17th, 1900. She gave the following history. In 1881, 1888, and in 1891 she was an in-patient at the London Hospital for "rheumatic fever." Whilst there in 1891 she had an attack of hypogastric pain similar to that which she had on admission to Charing-cross Hospital. It was not so severe and she felt nothing of it for twelve months after leaving that hospital. In 1893 she was in the Hastings Infirmary for three months for gastric ulcer and bronchitis and later for three months in the Chest Hospital. In 1894 she was an out-patient at the Grosvenor Hospital for Diseases of the Chest and an in-patient at King's College Hospital on two occasions. During her second stay at the latter institution she underwent an operation for fissure of the anus and hæmorrhoids. Since that time she had had long periods of illness. Two years ago, whilst at the Woking Nursing Home, she had another severe attack of hypogastric pain which came on suddenly and then left her. In August, 1899, she was on a visit to her sister at Cardiff and was suddenly taken ill. She was taken to the infirmary and apparently remained there till March, 1900. She said that during this time she had several periods of unconsciousness and also that her temperature ran an abnormally high course, ranging from 103° to 105° F. The last 14 days were marked by the onset of severe dysuria, the pain and frequency of micturition continuing and getting steadily worse after she left Cardiff. The patient was sent by her medical man to Charing-cross Hospital when she was discovered to be suffering from cystitis and was admitted.

On admission the patient was seen to be an ill-developed

individual. She was short and thin and looked unhealthy. Her conduct during her stay in the hospital convinced most of those who had to deal with her that she was a malingerer. She had always some fresh ache or pain to complain of, though when she was not being observed she was bright and cheerful. She made three consecutive attempts to produce hyperpyrexia. What method she used is not certain. The thermometer registered from 110° to 112° F. and then shortly afterwards the same instrument only recorded 99° if she was carefully watched. She complained on admission of a constant pain across the back and in the hypogastric region extending down the left leg. This was aggravated on micturition which occurred at first about every half-hour. Not only was there pain on micturition but also great difficulty. The urine was alkaline, of specific gravity 1013, and contained albumin and also pus. The evening temperature was usually 100°; the morning temperature was 99° or normal.

The patient's bladder was washed out with boric lotion once a day and she was given boric acid and ammonium benzoate internally. On May 22nd she was anæsthetised and the bladder was sounded by Mr. Morgan. A stone was found anteriorly and to the right. This was then crushed with a lithotrite. On washing out the bladder after several crushings particles of glass and globules of mercury were found to be mixed with the fragments of the stone. A pair of forceps was then introduced and some small pieces of stone and a piece of thermometer nearly an inch in length were removed. The débris thus removed was carefully collected, dried, and weighed, its weight being 12·31 grammes. It was then boiled with strong hydrochloric acid and filtered, leaving on the filter-paper glass and mercury. The filtrate was found to contain phosphate of calcium with a little uric acid. The remnants of the thermometer weighed 4·64 grammes, whilst a complete one weighed 6·1 grammes. The patient continued to pass particles of stone and mercury for a few days after the operation. There was some blood also in the urine. The pus gradually disappeared and the urine became acid. She still complained of pain on micturition and she was on two occasions sounded to find out if anything had been left behind. She was still complaining when she left the hospital on July 11th.

Remarks by Mr. MORGAN.—Amongst the many curious foreign bodies removed from the bladder this is the first instance in which a thermometer has been found. The patient was at first admitted under the care of Dr. Routh as her symptoms were referred to the uterus, and by him Mr. Morgan was asked to examine the bladder. The stone was easily detected and nothing unusual was suspected until the blades of the lithotrite closed upon a substance which yielded in a different manner to any of the substances ordinarily found to compose a calculus. At the first washing fragments of glass and mercury, together with some phosphatic deposit were removed, and the nature of the nucleus was thus disclosed. The previous statements of the patient and her general conduct forbade any reliance being placed upon her statements, but the weight and measurements of the fragments removed, the negative results of two subsequent washings, and the absence of any sign of irritation gave reasons for concluding that the whole of the foreign body had been removed at the first sitting. No trace of blood could be found in the urine a few days after the operation and micturition was called for only with normal frequency. As to how or when the thermometer was introduced through the urethra no cross-examination could elicit any information from the patient, but looking to her general behaviour whilst in the hospital there can be little doubt that it was done by her own act.

OPEN-AIR TREATMENT OF PHTHISIS.—At the meeting of the Bristol Board of Guardians held on August 3rd it was decided to apply to the Local Government Board for sanction to send two patients who were suffering from phthisis to the North London Hospital for Consumption, Mount Vernon, Hampstead, where the open-air treatment is adopted.

LUNACY IN SWINDON.—At the meeting of the Swindon Board of Guardians held on August 2nd it was reported that 142 patients from this union were inmates of the Wiltshire County Asylum, the cost for their maintenance being £3400 per annum. Ten years ago the guardians had only 66 cases in the asylum, at a yearly expenditure of £1160.

Reviews and Notices of Books.

A Manual of Pathology. By JOSEPH COATS, M.D. Glasg., late Professor of Pathology in the University of Glasgow. Fourth edition, revised throughout by LEWIS R. SUTHERLAND, M.B. Glasg., Professor of Pathology in the University of St. Andrews. London: Longmans, Green, and Co. 1900. Pp. xxv.-1132. Price 31*s.* 6*d.*

THE "Manual of Pathology" was the most important literary production of the late Professor Coats. It represents his life's teaching; it deservedly ranks as one of the standard works on pathology in the English language, and it owes that position to its undoubted excellence. It is well arranged, clearly written, and freely illustrated; it is so comprehensive that it leaves few points in the science altogether untouched; above all it is a manual for the student and the practitioner and not for pathologists only, for its author never forgets that pathology is essentially the foundation of medicine and surgery and he continually emphasises the clinical bearings of his subject. It is impossible to read the opening chapters of the book without feeling the value of a combination of clinical experience with pathological knowledge in one who would be a teacher of pathology.

This fourth edition of the work, unfortunately posthumous, had been in part revised by the author himself before his death. But the greater part of the work of revision, and hence a certain share of the responsibility, has rested on the shoulders of Professor Sutherland, who has conscientiously endeavoured to follow the lines laid down by Professor Coats. The task cannot have been an easy one, and though it is our duty to call attention to certain defects in the book it is certain that the work has been well done. Pathology is a vast and rapidly growing subject; it now embraces so many branches that it is doubtful whether anyone can hope to master them all. The development of experimental pathology, of pathological chemistry, of histology, and, above all, of bacteriology, has enormously increased the amount of ground to be covered by the student even since the first edition of this book was published. It is inevitable that with each succeeding edition of a book which seeks to be comprehensive the difficulty of including everything should become increasingly great and in time insurmountable. It is to our mind an open question whether it is any longer advisable to include in a single work so much as is attempted in this. The end can be attained only by an alarming increase in bulk or by inadequate treatment of certain subjects. It is clear that a book of over 1100 pages is as large as any ordinary student can be expected to master, and though the student who has mastered this edition will in most respects be well equipped in pathological knowledge it must be admitted that, as a universal work of reference on the subject, it is in other respects inadequate. As a text-book of morbid anatomy and morbid histology it is an admirable work; much of the information on general pathology—as, for instance, on inflammation and the various degenerations—is excellent and thorough; but there are sections on general pathology which are exceedingly scanty and imperfect—as, for example, the paragraphs on jaundice and albuminuria. The modern developments of hæmatology are practically neglected; leucocytosis is twice mentioned in a casual way, but its immense importance in diagnosis and prognosis is not touched on. Leukæmia is dealt with in almost as imperfect a manner, only a single reference being made to the all-important question of the absolute number of leucocytes per cubic millimetre. Bacteriology occupies 44 pages, and there is no fault to be found with the way in which the facts are presented. It is, however, doubtful whether it is wise to attempt to deal with

the details of the subject in so scanty a space. In the section on animal parasites malaria does not receive adequate treatment; in a work published in 1900 we might have expected some reference to the mosquito, since our definite knowledge as to the relation between it and the malarial parasite dates from 1898 at least.

If we have called attention to what appear to us deficiencies in this book it is because we are in duty bound to do so; but it is right to repeat that such deficiencies are almost inevitable and result from the natural growth of pathology beyond the possible limits of a single text-book. It is with much greater pleasure that we recur to the many good points of the volume. We have tested it as a standard of reference in daily work—the most severe test that can be applied to a book. It is but rarely that we have failed to find on any desired topic information sufficient for the ordinary needs of the student, conveyed in a clear manner and illustrated by a profusion of woodcuts and micro-photographs which are, as a rule, excellent. It is, indeed, the free use of illustrations—there are 490 in the text—which is partly answerable for the large size of the volume. The "Manual of Pathology" must long remain a standard work of reference for students, and Professor Sutherland is to be congratulated upon having carried out the designs of the original author in so successful a manner. But when, in the fulness of time, a fifth edition is called for, as will undoubtedly be the case, we would commend to his consideration the advisability of limiting in some measure the scope of the work.

Analytical Records
FROM
THE LANCET LABORATORY.

PLASMON.

(THE PLASMON SYNDICATE, LIMITED, 56, DUKE-STREET, GROSVENOR-SQUARE, LONDON, W.)

THE introduction of plasmon marks an important advance in the separation of the nutrient material without any deterioration of its dietetic quality from the most natural of all foods, milk. It is to be feared that in the preparation of many foods the process adopted seriously affects the nourishing qualities of the material in its original state. Chemical analysis may show an excellent proportion of flesh-forming constituents, but only physiological evidence can decide upon the real nourishing quality of the food product. Plasmon has satisfied both chemical and physiological inquiries. It consists practically of the casein of milk separated by a very simple process and dried. At no step in the process is objectionable chemical treatment introduced. Plasmon is a tasteless, odourless white powder which is entirely soluble in water though the solution exhibits a slight opalescence similar to that of milk. The dry powder swells up in water to a gelatinous mass which dissolves as more water is added. On boiling the solution a "skin" continually forms at the top of the liquid in the same manner as in fresh milk. The important dietetic salts of milk are retained in the preparation. Everybody is familiar with the effect of mixing aerated water with milk, the casein separating in fine digestible curds and not in voluminous indigestible clots. Further, it is well known that soda-water-and-milk is an excellent beverage and food for the invalid, especially where sensitive conditions of the digestive organs exist. Plasmon is practically the casein of milk thus separated and afterwards dried in a stream of the same gas (carbonic acid) which separates the proteid from milk serum. Our analysis of plasmon gave the following results: moisture, 10·76 per cent.; mineral matter, 7·24 per cent.; milk fat, 0·70 per cent.; proteids, 81·30 per cent. Excluding the moisture these results mean that dry plasmon contains over 90 per cent. of pure proteid. That this proteid thus separated retains its powerful nourishing qualities is evident from the interesting experiments made by Professor Virchow. He concludes that the albumin in plasmon is in its original unaltered condition, and therefore plasmon can replace all other albumin foods. He finds, further, that it is extremely digestible, and in some interesting experiments made upon himself in which the diet consisted almost entirely of plasmon the results were highly satisfactory. Plasmon has accordingly been found of great value as a nutrient in enfeebled conditions of the digestive organs and to be an excellent means of administering food to the sick. It is valuable as a prelude to solid food for patients convalescing after disease or after surgical operation. It is important to point out that plasmon contains, as our analysis shows, the salts of milk including the phosphates, while even a small quantity of common salt may be extracted from it. It is obvious that plasmon may be employed with the greatest advantage for enriching foods or for raising their actual flesh-forming value to a high and trustworthy degree. The variety of ways in which plasmon may be prepared need not be enumerated when regard is had to the fact that it is soluble in water. Thus a powerful nutrient may be administered to a patient without his knowledge, for, as we have already stated, the solution of plasmon is practically tasteless and odourless. The preparation is one worthy of the highest praise. It contains no alkali and is permanent for an indefinite period in the dry state. Chemical analysis shows what a remarkably high proportion of proteid it contains, and physiological experiment has established that this proteid is completely available for the nourishment of the human body.

(1) NEW TABLOIDS; (2) HIGH POTENCY ANTI-DIPHTHERITIC SERUM; AND (3) "ENULE" RECTAL SUPPOSITORIES.

(BURROUGHS WELLCOME AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

Some comparatively recent additions to the list of tabloids are well worth the attention of our readers. The success which has attended the administration of codeine in place of morphine has suggested the preparation of tabloids containing a quarter of a grain and half a grain respectively of the alkaloid. Unlike morphine, codeine may be withdrawn from administration without being followed by unpleasant symptoms. It acts as a narcotic in the relief of pain in the same way as morphine but is less active, and is free from injurious after-effects. As is well known, the drug has proved useful in the treatment of bronchial irritation and cough, while its administration reduces the quantity of sugar in the urine of diabetic patients. Chinosol has been some time to the front now as a convenient bactericide and antiseptic in surgical work. It has also been tried internally in the treatment of tuberculous diseases. Again, it has been administered in febrile conditions which accompany leprous ulcerations and in dysentery. Lately it appears to have acted as a satisfactory febrifuge in typhoid fever. The tabloid of chinosol contains five grains of the salt. The tabloid of urotropine contains five grains of this ammonia derivative (hexa-methylene-tetramine). It has been used as a diuretic and genito-urinary antiseptic, while there is evidence also to show that it acts as a solvent of uric acid and urates. Urotropine is claimed to have been of distinct service in cystitis. Messrs. Burroughs Wellcome and Co., it is important to note, have discontinued the issue of anti-diphtheritic serum in vials containing 1500 units in favour of serums of higher potency. Each vial of the more powerful serum contains 4000 units in five cubic centimetres or less, or vials containing 2000 units in five cubic centimetres or less may be obtained. The rectal suppositories

made by this firm are distinguished by the brand "Enule." We have recently received specimens of "Enule" opium suppositories containing one grain of opium. As is well known the administration of opium per rectum has, besides acting locally, a favourable action in obstinate vomiting and in painful nephritic and uterine affections.

HEREFORDSHIRE CIDER.

(H. P. BULMER AND CO., RYELANDS, HEREFORD.)

The specimens sent for examination were distinguished by the following titles: (1) Cherry Pearmain; (2) Cherry Pearmain, extra dry; and (3) Draught Cider. The results of analyses were as follows. Cherry Pearmain: alcohol, by weight 5·25 per cent., by volume 6·55 per cent., equal to proof spirit 11·49 per cent.; volatile acid reckoned as acetic acid, 0·096 per cent.; fixed acid reckoned as malic acid, 0·24 per cent.; extractives, 6·09 per cent.; sugar, 5·8 per cent.; and mineral matter, 0·27 per cent. Cherry Pearmain, extra dry: alcohol, by weight 4·62 per cent., by volume 5·78 per cent., equal to proof spirit 10·13 per cent.; volatile acid reckoned as acetic acid, 0·16 per cent.; fixed acid reckoned as malic acid, 0·18 per cent.; extractives, 1·95 per cent.; sugar, 0·26 per cent.; and mineral matter, 0·23 per cent. Draught Cider: alcohol, by weight 5·87 per cent., by volume 7·32 per cent., equal to proof spirit 12·84 per cent.; volatile acid reckoned as acetic acid, 0·12 per cent.; fixed acid reckoned as malic acid, 0·23 per cent.; extractives, 2·36 per cent.; sugar, 0·28 per cent.; and mineral matter, 0·25 per cent. The results of these analyses practically divide the specimens into the two classes, "sweet" and "dry," the draught cider presenting a similar composition to the extra dry contained in bottle. In these two specimens the sugar does not exceed one-third per cent., while the ordinary Cherry Pearmain in bottle contains over 5 per cent. of sugar, which accounts for the high amount of extractives. All three specimens were in excellent condition and sound and no objectionable preservatives could be traced. The "extra dry" specimen possesses the marked and very pleasing fragrance characteristic of the apple and is a very wholesome and refreshing drink. Those who prefer cider in which the fermentation is not so complete, and therefore in which the sugar has not "worked out," may select the more or less sweet kinds. The specimens were brilliant and agreeably effervescent. There is abundant evidence tending to show that cider is a healthy beverage during the hot summer months. The above brands may be recommended in view of their purity and excellent quality.

HIGHLAND MALT WHISKY.

(J. S. WHERLY AND CO., 129, ASKEW-ROAD, GATESHEAD.)

On analysis this spirit proved to be free from excessive extractive matters and exhibited a fair average alcoholic strength. The results were as follows: alcohol, by weight 40·30 per cent., by volume 47·67 per cent., equal to proof spirit 83·54 per cent.; acidity reckoned as acetic acid, 0·021 per cent.; extractives, 0·23 per cent. The whisky was relatively light in colour and to the taste was satisfactory. It was free from the common impurities of whisky.

THE "GYE PROCESS" FRESH FOODS.

(THE GYE PROCESS FRESH FOODS (NEW) CO., LIMITED, SUNBURY, MIDDLESEX.)

We have formed a very favourable opinion of these foods, which are preserved without the addition of antiseptics and by a process which, though evidently a desiccating one, is in no sense a process of cooking, for on examination the specimens sent were found to have retained all the properties and characters of the fresh article. We found that on following the directions given the dried-up preparations could be restored to their original bulk and on subsequently cooking they were found to retain to a somewhat remarkable degree the attractive properties of the freshly cooked food. This satisfactory result was true not only in the case of the vegetables but also of the animal foods and the "ration block." Amongst the samples submitted to us were the following: turnips, leeks, carrots, apples, artichokes, onions, cabbage, chicken, veal, eggs, beef, ration block, &c. On trying the specimens of vegetables we found the product after soaking and cooking to be quite tender and to possess a good fresh flavour. These results are very encouraging and afford some evidence that an excellent way has been found of preserving many kinds of foods without the addition of chemicals and without cooking, the products retaining all the properties of the fresh article. As far as we can gather the process would appear to consist of extracting the moisture by special means without altering any of those particular qualities which are destroyed by cooking.

MEAT ESSENCES.

(F. B. COSTA AND CO., 16, DOWGATE-HILL, CANNON-STREET, E.C.; AND GEORGE BAGGER AND CO., PIAZZA SAN BERNARDO 100, ROME.)

The specimens examined were (1) essence of beef and (2) turkey jelly with meat. The former was found to contain the constituents of raw meat juice of which unaltered albumin is the most important. The essence is of excellent flavour and is especially valuable for invalids, since it is easily digested. The latter preparation was found to contain the meat of turkey in addition to the soluble portions. Meat fibre was easily identified under the microscope. It possesses a very pleasant flavour and yields a broth which should be acceptable to invalids. Both preparations are so excellent that it is a pity that the makers cannot contrive to preserve them in glass jars rather than in tins. As a matter of fact we found evidence of some metallic contamination.

HELIDON SPA WATER.

(THE HELIDON SPA WATER CO., HELIDON AND BRISBANE. LONDON AGENCY: IDRIS AND CO., CAMDEN TOWN, LONDON, N.W.)

We have made a careful analysis of this water, which is said to be drawn from the natural spring of Helidon, Brisbane, Australia, and the following results were obtained: carbonate of soda, 183·32 grains per gallon; common salt, 46·57 grains per gallon; and carbonate of calcium, 9·87 grains per gallon. The total mineral constituents are thus 239·76 grains per gallon. We could only find lithia in traces—that is to say, hardly in a quantity to justify the water being called a lithia water. In an analysis published on the label of the bottle we notice that 2·68 grains per gallon of lithium carbonate are said to be present. Assuming these figures to be correct it would not be true to state that "this water contains more lithia than any of the European spa waters." Further, the quantity of chloride of sodium given in the analysis on the same label is 2·99 grains per gallon, whereas we found over 46 grains per gallon. These figures are so discordant as to suggest that the water is liable to important variations in composition. The water has a very agreeable and soft taste, is free from iron, and pleasantly sparkling. Moreover, it contains no organic impurity.

DIETETIC PREPARATIONS.

(COOMBS EUREKA AERATED FLOUR COMPANY, LIMITED, NOTTINGHAM. LONDON AGENCY: 8, FARRINGDON-ROAD, E.C.)

An assortment of food preparations sent to us by the above firm comprised malted food, fruit salt, custard powder, blancmange powder, egg powder, and light pastry powder. The preparation possessing most merit, perhaps, is the malted food. Its title sufficiently explains its composition. By the method adopted the food is undoubtedly enriched and made more assimilable. The fruit salt consists of a powder which effervesces on adding water and its composition presents no novelty. The custard powder consists largely of starch faced with yellow colouring to give it the appearance of eggs, but in no sense can this powder be regarded as an

efficient substitute for the true custard made from eggs. It contains but a trifling proportion of flesh-forming materials. The blanc-mange powder is similarly composed, as is also the egg powder. The word "egg" in the latter case is a decided misnomer, implying eggs where no shadow of eggs is. Lastly, the light pastry powder consists of flour containing a small addition of ingredients which yield carbonic gas on moistening. Thus the product is made spongy and light by the disengagement of the gas during cooking.

HÆMOGLOBIN CAPSULOIDS.

(THE CAPSULOID CO., 31B, SNOW-HILL, LONDON, E.C.)

According to our examination these capsuloids contain hæmoglobin in an oily excipient. The contents of one capsuloid weigh a little more than three grains, and according to our analysis the proportion of iron is 0·30 per cent. The administration of iron in this form is satisfactory. Hæmoglobin is well borne by the stomach and easily assimilated. To not a few the appearance of hæmoglobin preparations is repulsive. The capsuloid meets this objection, and evident care is devoted to its preparation.

(1) SAVON DU TRANSVAAL; AND (2) SAVON SURFIN.

(MADAME ESMÈE, 5, BROOK-STREET, LONDON, W., AND BLANCHE LEIGH, 4, RUE DE LA PAIX, PARIS.)

Both specimens consist of delicately prepared soaps, neutral in reaction, free from irritants and resins, and therefore, apart from medication, suitable for delicate skins. But the soaps are regarded as antiseptic and also of some curative value on account of the presence of ichthyol. Ichthyol is, of course, of well-known value in various skin diseases, but we do not think that the very small amount present in these toilet soaps can avail much in this direction. On distillation with alkali the yield of ammonia was quite minute. Since ichthyol is an ammonium salt this result indicates but a very small proportion of this curious product. For external application ichthyol is used in an ointment containing from to 50 per cent.

CHELTINE FOODS.

(WORTH'S FOODS SYNDICATE, LIMITED, CHELTENHAM.)

We have on a previous occasion described the composition of the "diabetic food" of this company. Since it contains an abundance of carbohydrates it cannot be accepted as in the least degree suitable for diabetic patients. On the contrary, it would be harmful. We have also examined certain other foods prepared by this company, notably, "Perfect Food" and "Dyspeptic Food." We have devoted our attention chiefly to the proportion of soluble and digestible matters in these foods and to the evidences of a microscopical examination. The results were satisfactory and indicated that the foods had been prepared with the view of aiding the digestive processes. Their names, therefore, to some extent are justified. Further, we found that the foods contained an excellent proportion of the cereal phosphates and of the nitrogenous constituents. The flour used is evidently of superior quality.

PETANELLE DISINFECTING POWDER.

(PATE, BURKE, AND CO., 6, WOOL EXCHANGE, BASINGHALL-STREET, LONDON, E.C.)

Besides being itself a disinfecting agent on account of its porosity this curious substance is a most excellent vehicle for absorbing disinfectants to be applied for domestic purposes. Petanelle possesses the undoubtedly advantageous property of floating upon water, so that by keeping a film of an oily disinfectant upon the surface of water offensive gases are effectually deodorised. Moreover, the substance is so light as to be easily swept away by a flush of water so that it would not block the pipes. It is an interesting peaty product, very porous, and an effective absorbent—a property which adapts it admirably for hygienic and disinfectant purposes. Petanelle, it may be added, is used in the preparation of a surgical woo and of a variety of hygienic fabrics, such as clothing, abdominal belts, &c.

V. O. SCOTCH WHISKY.

(FINDLATER, MACKIE AND CO., 16, PRINCE ALBERT-STREET, BRIGHTON.)

Judging from the peculiar softness and mellowness of its flavour, which, of course, is a very satisfactory feature, this spirit has been properly left to mature. It is stated to be 10 years old. The results of analysis were as follows alcohol, by weight 43 24 per cent., by volume 50·82 per cent., equal to proof spirit 89·06 per cent.; acidity reckoned as acetic acid, 0·033 per cent.; extractives, 0·48 per cent. mineral matter *nil*. These figures show an alcoholic strength which is somewhat above the average for whisky. We have no doubt that this whisky is derived from genuine materials. It possesses a flavour characteristic of malt and is as free as it is possible to be from objectionable alcohols.

ALBUMEN PASTE.

(THE NAO FOOD COMPANY, 2, GREAT GEORGE-STREET, LONDON, S.W.

We have carefully examined this "paste" and have found it to be correctly described. The major portion of the albuminous substances of meat was present in an insoluble but finely-divided condition. We obtained, however, a cold water extract which proved to contain a notable quantity of coagulable albumin. The "paste" also contains fat. The flavour is good and therefore we may regard the preparation as both an acceptable and a highly nourishing food.

ASYLUM REPORTS.

Saint Andrew's Hospital for Mental Diseases, Northampton (Annual Report for 1899).—The average number of patients in the institution during the year was 377, comprising 186 males and 191 females. The admissions numbered 103, 35 being those of males and 68 those of females. Of these 19—viz., 6 males and 13 females—were re-admissions. The number of admissions has continued to increase steadily for the year 1899, as compared with 86 for the previous year and 73 for the year 1897. During the year 36 patients were discharged as recovered—viz., 14 males and 22 females—a total of 9·5 per cent. of the average number resident. The deaths during the year amounted to 22—viz., 17 males and 5 females—a total of 5·8 per cent. as calculated on the same basis. Mr. Joseph Bayley, the resident medical superintendent, states in his report that "the death-rate on the male side of the hospital has again been high, 17 out of 22 deaths having occurred on that side. ..... Two male patients were found dead in bed, and both these cases happened within a week of each other and under similar circumstances. ..... Post-mortem examinations showed that death in both these cases was the result of heart disease." Notice was sent to the coroner and an inquest was held on the second of these cases and a verdict of "Death from heart disease" was returned. Two accidents with fractured bones, one a fracture of the knee-cap and another of the femur, occurred on the female side. Both patients made good recoveries. Of the deaths during the year two each were due to phthisis, cardiac disease, and cancer respectively, three to general paralysis of the insane, the same number to acute mania, and four to senile decay. Early in the year the committee of management made an order that after March 31st no persons should be employed in the hospital or in the houses belonging to it who could not produce satisfactory evidence that they (and the residents in their houses) had been vaccinated. Seven persons refused to comply with this rule and resigned their situations. A fire broke out in the kitchen and extended to the roof, but was extinguished by the fire brigade without serious results Plastering and other alterations on the male side which have long been delayed by a strike of the plasterers are now completed. The new house for the boilers and electric light apparatus, engines, dynamos, &c., is now completed. The financial condition of the hospital continues to be very satisfactory, but there is a loss of £115 on the farm. The general health of the establishment is good, and with the exception of one case of measles the hospital has remained

free from epidemic or zymotic disease. The Lunacy Commissioners state in their report that the hospital and villas are maintained in excellent order.

West Sussex County Asylum, Chichester (Annual Report for 1899).—The number of patients on the books at the beginning of the year 1899 was 466. The average number resident during the year was 478 patients, and comprised 217 males and 261 females. During the year 100 cases were admitted—viz., 39 males and 61 females. Of these five—viz., two males and three females—were cases of re-admission. Mr. H. A. Kidd, the medical superintendent, states in his report that the causes tending to inflate the admission rate of West Sussex patients during the first year or two after the opening of the asylum have now ceased to exist. "But unfortunately there has been an increase of 20 in the numbers on the female side, and although there is but one female in the building not belonging to West Sussex there are already 15 patients in excess of the number of beds originally provided. The extensions which have been planned and which are now being carried out will provide 200 extra beds for females and 100 for males, and may possibly be ready for a partial occupation at the beginning of next year. By that time," says Mr. Kidd, "it is to be feared, the difficulty of providing accommodation for female patients will have become very acute." The character of the admissions, regarded from the point of view of recoverability, was even worse than during the previous year. Thus, of the 100 patients admitted recovery was considered reasonable probably only in 25 cases—viz., in those of 14 males and 11 females. "These are the cases for whom the institution is strictly a hospital. They afford scope for energetic treatment directed to the improvement of the physical ill-health ..... and to the cure of the mental disorder which needed certification and removal from home." Among the cases regarded as hopeless of recovery were those of 10 patients whose mental breakdown was consequent on senile brain degeneration and 11 congenital cases—patients who had either been born with defective brains or whose brain development had been arrested in infancy. Seven of the admissions were cases of general paralysis and five of the patients were in the last stage of mental decay. Dealing with the causes producing the mental diseases it was ascertained that heredity was a predisposing cause in 41 per cent. of the cases, alcoholic excess was ascertained to be the cause in 14 per cent., and several cases were traced to influenza. "The tendency to nervous breakdown following this very troublesome disease emphasises the great importance of careful treatment continued after the primary attack, even though slight, is past." In 23 instances there had been previous attacks of insanity. Among the moral causes the adversities and trials of life, emotional excitement, and domestic or business worries accounted for 26 per cent. of the cases. 35 patients were discharged as recovered during the year, or 7·5 per cent. of the average number resident. There were 32 deaths during the year, 18 being males and 14 females, or 6·7 per cent. of the average number resident. Necropsies were made in every instance and the fact that a bedsore was discovered in a single instance only is practical evidence of good nursing. Of the deaths during the year two were due to pneumonia, four to influenza, four to phthisis, three to general paralysis of the insane, seven to senile decay, and eight to organic brain disease. At the outbreak of the war in South Africa more than half of the male staff were reservists, and in the first week after the calling out of the reserves seven attendants left to join the colours. It was decided by the committee that their places should be kept open for the men while on leave. "The work of filling up satisfactorily the gaps so suddenly created in the staff has been a difficult and anxious task." The casualties during the year included fractures of the arms in two female patients and a fractured femur in a male patient. An epidemic of influenza occurred just after Christmas, about 50 patients being affected. A case of diphtheria occurring in the wife of an employé was treated in the sanatorium. 76 per cent. of the men and 85 per cent. of the women are occupied in some form of work or employment. Additions and alterations involving an expenditure of £236 have been carried out in the general stores, the butcher's shop, the laundry, and the wards. Improvements have been made in the electric light supply. The working of the farm shows a credit balance of £333. The Lunacy Commissioners in their report state that the case books are kept with care and intelligence and that pathological work is carried on.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE annual meeting of this association was recently held under the presidency of Dr. FLETCHER BEACH.

On the morning of Thursday, July 26th, the officers and council for the ensuing year were elected and the reports of the Parliamentary and Education Committees were read and adopted. Seven ordinary and three honorary members were elected. It was also resolved that a copy of the following resolution should be sent to the Local Government Board in the three kingdoms: "It is the unanimous recommendation of the Medico-Psychological Association of Great Britain and Ireland that in union workhouses in which insane persons are detained a properly qualified and trained mental nurse should be employed in the insane wards."

In the afternoon Dr. SPENCE vacated the presidential chair, which was taken by Dr. FLETCHER BEACH, who delivered his presidential address. After referring to the losses which the association had sustained by the deaths of some prominent members during the year he gave an account of the progress which had been made in the treatment of certain defective classes of society, such as idiots, imbeciles, the feeble-minded, the epileptic, and juvenile delinquents, during the last 60 years. He described the labours of Séguin, who was the originator of the system of educating and training idiots and imbeciles which is now in use, as well as of Saegert and Guggenbühl, who were pioneers in the work. He then traced the progress of educating and training idiots and imbeciles in England and described the way in which the Earlswood and other charitable asylums were erected, as well as the one for paupers at Darenth. Reference was also made to the institutions which have been built in Scotland and Ireland. An account was then given of the progress of the work in America from the time of the opening of the Massachusetts and New York Asylums for Idiots in 1848 and 1851 respectively, down to the present time, and it appeared that there are now no less than 19 States which maintain 24 public institutions, providing accommodation for 8492 inmates. An account was also given of the provision made in France, Germany, Denmark, Norway, Switzerland, Austria, and other European States, in our colonies, and in the Argentine Republic for this class of cases. Dr. Fletcher Beach fully described the way in which the education of feeble-minded children originated in England from the time when the British Medical Association first in 1888 appointed a committee to inquire into the subject to the present day. Full credit was given to the labours of Dr. Warner and of various committees which have inquired into the subject, and it was stated that the Childhood Society now carries on the work. Reference was made to the Departmental Committee which was appointed to inquire into the systems now in force for the education of feeble-minded children, and a short account was given of the Elementary Education (Defective and Epileptic Children) Act which was subsequently passed. The labours of the National Association for Promoting the Welfare of the Feeble-Minded were also referred to, and it was shown that England, in spite of the work of the London and other school boards who have established special classes, is still far behind many continental countries. The provision made for epileptics was described, and it was shown that it is only in recent years that accommodation has been specially made for the sane and insane patients of this class. In providing for epileptics, as well as for idiots, imbeciles, and the feeble-minded, England has lagged behind, but it is satisfactory to know that there are now three colonies and there will soon be a fourth for sane epileptics, and that the Chorlton and Manchester and the Leicester Boards of Guardians, as well as the London County Council and Lancashire Asylums Boards, are about to erect colonies for the epileptic insane. A short account was then given of the way in which juvenile delinquents are now treated, from which it appeared that it was not until 1854 that reformatory treatment of criminals was substituted for retributive punishment. In 1896 there were 50 reformatories and 141 industrial schools, accommodating altogether about 22,000 youthful offenders.

Dr. WYNN WESTCOTT, coroner for North-east London, and

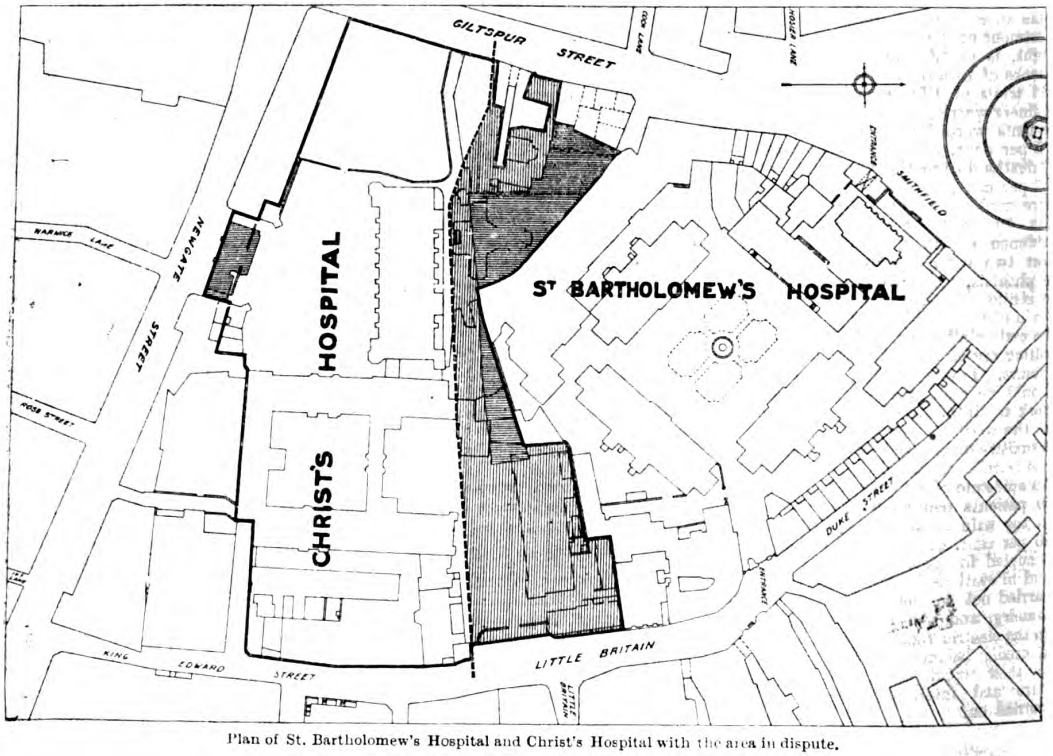
President of the Society for the Study of Inebriety, then read a paper entitled Inebriety, its Causes, Results, and Treatment. He reviewed the present opinions on the causation of inebriety and especially the question of inherited tendency to the drink-crave, touching upon the debated point of the possibility of inheriting an acquired inebriety. He pointed out the follies of the numerous claims to the cure of inebriety by secret medicines and processes and expressed his confidence in the treatment of inebriates in licensed reformatories by recognised therapeutic means.—The paper was discussed by Dr. FORMAN, vice-chairman of the committee of the London County Council for providing Inebriate Asylums, Dr. MORTON, Dr. HEYWOOD SMITH, Dr. ARCHDALL REID, Dr. STEWART, and others.

On Friday morning, at 10 o'clock, Mr. HAYES NEWINGTON exhibited and described the Plans of the new East Sussex Asylum, in which a hospital for 250 cases is a prominent feature. Provision is also being made for 60 idiot children in a separate building. Some villas were being built for the accommodation of male cases and it was intended to erect more as time went on.—The paper was discussed by Dr. CLOUSTON, Dr. ROBERT JONES, Dr. TURNBULL, Dr. MERCIER, and others, and Mr. NEWINGTON replied.

The rest of the morning was devoted to lantern demonstrations by Dr. ORR, Dr. COWEN, Dr. G. A. WATSON, Dr. BARRETT, and Dr. J. TURNER by which the Morbid Anatomy of General Paralysis of the Insane, Juvenile General Paralysis, Lepto-meningitis, and alterations produced by Disease in the Giant Nerve-cells of the Cortex were fully pointed out and it is evident that some of the younger members of the association are doing good work.

Dr. SHAW BOLTON exhibited some naked-eye preparations and specimens from the Museum of the Pathological Laboratory of the London Asylums at Claybury and Dr. CLOUSTON showed for Dr. FORD ROBERTSON a microscopical demonstration of the Normal and Pathological Histology of Mesoglia Cells.

In the afternoon Dr. BRUCE read a paper prepared by himself and Dr. ALEXANDER on Observations upon the Various Physical Changes in the Acute and Sub-acute Stages of Melancholia in which he pointed out that among other changes there was increased blood-pressure and a decreased excretion of urea and urine in the acute stage and not such high pressure and more abundant excretion of urea and urine in the sub-acute stage. In the acute stage the blood-pressure should be reduced by, among other remedies, rest in bed and vapour baths.—The paper was discussed by Dr. CLOUSTON, Dr. MICKLE, and others and Dr. BRUCE replied.



Mr. BEADLES read a paper on the Insane Jew, in which it was mentioned that general paralysis was common among Jews but epilepsy was rare.

Papers were afterwards read by Dr. SULLIVAN on Alcoholic Homicide, Dr. BLAIR on Non-diabetic Glycosuria, Dr. SHOYER on an Angeioma of Broca's Convolution in a Lunatic, and by Dr. EDRIDGE-GREEN on Psycho-physical Perception, but want of space prevents a description of them being given.

The annual dinner was held on Thursday evening, July 26th, at the Whitehall Rooms, Hôtel Métropole, at 8 P.M., the President, Dr. FLETCHER BEACH, being in the chair. On Saturday the President and Mrs. Fletcher Beach were "At Home" to members and their friends at Kingston Hill. Fortunately the atmospheric disturbance of the previous day had passed off, and the re-union of members and their friends brought to a close a very successful meeting.

ST. BARTHOLOMEW'S HOSPITAL AND CHRIST'S HOSPITAL.

THE accompanying plan shows very clearly the areas at present occupied by St. Bartholomew's Hospital and Christ's Hospital respectively. The land that St. Bartholomew's Hospital desires to acquire lies immediately on its southern boundary, being all that part of Christ's Hospital north of the broken line drawn from east to west across the plan. It is 1 acre 1 rood and 29 poles in extent. In the year 1819 Christ's Hospital was pressed for space and at their request St. Bartholomew's Hospital then gave up to them in exchange for other property a considerable part of the identical land that the latter now wishes to re-acquire. The authorities of St. Bartholomew's Hospital did not then foresee the urgent need that would subsequently arise for most of the very land which they were then parting with. That land is shaded horizontally. Almost the whole of the frontage that Christ's

Plan of St. Bartholomew's Hospital and Christ's Hospital with the area in dispute.

Hospital now possesses in Newgate-street was included in that exchange. The St. Bartholomew's minutes of the time record that the exchange was made for "the conveniency of Christ's Hospital" and that in assenting to it St. Bartholomew's Hospital was "actuated by the most liberal motives" towards that institution.

FACTORIES AND WORKSHOPS IN 1899.

II.[1]

No one can study the report of the Chief Inspector of Factories without being struck with the wide range of the work to be done by factory inspectors and the variety of the causes which make their work difficult to carry out effectively. That their duties are not limited to those most obviously suggested by the title "inspector" will be appreciated by all who remember that, as a rule, they have to conduct their own prosecutions. This necessarily implies being frequently pitted in a court of law against a skilled advocate accustomed to handle the tribunal before which he appears, while the tribunal itself may be composed of borough magistrates personally acquainted with the accused, themselves involved in similar trades and equally liable to inspection and prosecution. In an extreme instance (given at p. 247) a Bench mainly composed of local fellow-traders refused to convict in spite of the plain meaning of the Act, and in spite of the opinion of the stipendiary magistrates present that on the facts disclosed in evidence there was no possible alternative, the Bench finally refused to state a case for the opinion of a higher court in face of the authoritative demand of the representative of the Attorney-General for Ireland. That this should occur in the distressful country is not surprising, although it is a little disconcerting to those concerned in such prosecutions to find the compulsory protection of the working poor against the dangers of labour treated as another injustice to Ireland.

A glimpse of the difficulties attending the enforcement of Factory Acts in extreme cases may best be given by quotation from the report of Miss Deane, one of two lady inspectors temporarily employed during the past year in Donegal. "The struggle in which we found ourselves engaged," she writes, "involved a study of Irish law procedure which cannot but be invaluable to us, and has been carried on with a courage and tenacity which can only be described as dogged on the part of Miss Squire, who has lived for the most part practically under police protection, and who was much cheered by the undoubted sympathy and gratitude of the peasants on whose behalf she fought. ..... Nothing but a saving sense of humour could alleviate the misery of the long car drives of 18 and 20 miles which I took at 5.30 on dark and stormy mornings in November and December in pouring rain to fetch witnesses to the courts, no car-driver in the neighbourhood being available or willing to incur the consequence of aiding 'the Government' by bringing in the witnesses." It is consoling to read the above reference to the gratitude of the peasants on whose behalf all this was done by two ladies who, in the course of the year, travelled 9916 and 8518 miles respectively, but it is also possible to think that in cases of difficulty in which a great deal of time and labour are likely to be expended legal assistance should be afforded to the inspector who, whether man or woman, probably has not too much time in the year for the efficient performance of the primary duty of inspection.

The report of the medical inspector, Dr. T. M. Legge, is the last one given and is naturally one of the most interesting and one of the most important. Nearly half of it is occupied with particulars and comments bearing upon the existence and prevention of lead poisoning. This is not surprising when the numerous industries are taken into account in which lead poisoning may occur. We have spoken of the use of lead in the glazing of earthenware and of the possibility of the danger from its use being lessened in the future either by the observance of the precautions prescribed by the Home Office or by other processes of glazing being substituted for it, and we note another instance of the disuse or improved use of a dangerous substance in the case of glass polishing with putty powder. Putty powder, it is stated, has been dispensed with altogether in certain kinds of work, but as nothing else at present imparts the same brilliancy, putty powder is still used for certain high-class work, such as the polishing of lenses, but it can be and is mixed with wax or pitch which prevents "splashing." In addition, however, to the danger arising from the actual smelting of lead, the manufacture of red and white lead, and the manufacture of china and glass, it must be remembered that lead poisoning has occurred in ironworks and has to be guarded against, to give some instances, in file-cutting, printing, tinning and enamelling hollow ironware, and enamelling iron plates, in several of the processes connected with the manufacture of electrical accumulators, in various kinds of painting, and in the employment of red and white lead, as, for example, in shipbuilding yards. Lead-poisoning is also one of those dangers in which the precautions to be taken do not only rest with the employers but in which the apathy of the workers themselves has to be contended against. As to this Mr. E. H. Osborn, the "engineering adviser," has an interesting note. He writes: "I have been much struck with the variations of the personal factor among the workers in this manufacture; of course, similar dissimilarities are to be found in all industries where so much depends upon personal care, cleanliness, and common sense, without which no code, however searching, can secure its fair success. I noticed a marked contrast between the workers on the opposite sides of the Tyne in these respects. ..... It is odd, too, that personal neglect is more usual among women than among men. This seems of almost universal application in the scheduled trades." Mr. Bond, certifying surgeon of Poole, writing apparently of female decorators in china works in Dorset, says: "I attach the greatest importance to constant and incessant supervision, a doctrine very repugnant to the workers who entertain a great regard for the liberty of the subject."

To pass to other topics dealt with in the medical inspector's report we find interesting notes from Mr. Farnfield, dentist to the Diamond Match Company, Liverpool, on the work done by him. He found about 6 per cent. of those who needed treatment before proceeding to work were prevented either by their own fears or by the ignorance of their parents from availing themselves of his services, and he continues: "With regard to the new hands I have passed 554 into the phosphorous rooms and 271 into the box-room, rejecting altogether 40 per cent. of those examined from bad teeth and gums. They were mostly in a very dirty state, few ever having cleaned their teeth prior to entering the factory. This makes it difficult to determine during a brief inspection the number of fillings they require, but I have noted down 869 fillings and 604 extractions, or, allowing for omissions, an average of two fillings and one extraction for those admitted into the phosphorous rooms and 601 fillings and 739 extractions, or an average of three fillings and three extractions for those to the box-room. ..... The greatest difficulty is at present in getting the requisite number of boys, as their teeth are mostly in a very bad state, and it is very difficult to persuade the average lad of 14 years to trouble at all about them." It will be recollected that the same difficulty occurs in the obtaining of suitable recruits for Her Majesty's army and navy, and it may be suggested that if the compulsory use of the tooth-brush were instituted in public elementary schools it might be classed by some under the heading of "grandmotherly legislation," but it is no more "grandmotherly" to make a child brush his teeth than to compel his parent engaged in a dangerous manufacture to wash before eating or to wear a respirator.

Among other matters dealt with by Dr. Legge we note that he gives the rules in force in the German empire for the prevention of anthrax from handling hair and bristles, as requiring the disinfection of all material not liable to serious damage by such processes as follows: either (1) by the action for at least one half-hour of current steam under a pressure of 1·15 atmospheres; (2) by boiling for at least one quarter of an hour in a 2 per cent. solution of potassium permanganate and subsequent bleaching in a from 3 to 4 per cent. solution of sulphurous acid; or (3) by boiling in water for at least two hours. In order to make the steam process effective, Dr. Legge points out, the bales must be opened—in itself a task involving some danger. Attention is called on another page to the frequent occurrence of tetanus, where workers in jute mills have met with injury; with regard to this Dr. Legge suggests that the soil in which the jute is grown may be particularly rich in tetanus bacilli and states that inquiry is being made in India as to the incidence of tetanus among jute workers there. The usual complete tables are appended to the reports upon which we have commented.

[1] No. I. was published in THE LANCET of July 28th, 1900, p. 285.

THE LANCET.

LONDON: SATURDAY, AUGUST 11, 1900.

IT has been a pleasure to us to report with some fulness the proceedings of the First International Congress on Medical Ethics or Deontology held in Paris, and extending over four days, beginning on July 23rd. Our Special Commissioner has done much by his investigations into the state of medical organisation in Great Britain and in several foreign countries to prepare the way for this Congress, and all the subjects dealt with are of particular interest to our readers. The ethics of medicine are as old as HIPPOCRATES, if they are not older, and it is a proof of their strength that they have for so many ages been recognised and more or less acted on by members of the profession in every part of the world. Of late years, owing to great changes in society and in the organisation of its various classes, it has appeared to many that more definition of ethical principles and a completer organisation of the profession are necessary for the guidance of its members that they may maintain their high position in the esteem of mankind. Accordingly various societies in different countries have been instituted for the purpose of defining, declaring, and enforcing these principles. Most of these societies have arisen out of voluntary effort. Others, as those in Austria and Germany, have been established by law and have been endowed with strong disciplinary powers over all members of the profession. A Congress at which representatives and delegates from the principal of these societies were present must have a powerful effect in helping medical men to assert the claims of the medical profession and to uphold its dignity in their several countries.

The foundation of medical ethics rests on the fact that the relations of the medical profession to society and to its individual members are so serious and confidential as to necessitate a special code of conduct for medical men, while the dignity of the profession depends on the degree to which its individual members respect themselves and respect each other. Dr. GRASSET quoted DESCHAMBRE as saying that for medical dignity to be respected the medical man must first be imbued with the sentiment of self-respect. And he developed this sentiment admirably by saying: "The medical man will first seek to honour his profession by honouring himself. Placing himself beyond the possibility of reproach he will pay every deference to his colleagues and be guided by the sentiment of duty and honour, not by the desire of material gain. If the public are to respect medical men the latter must first respect each other." If such principles could be implanted in all medical men there would be little need of medical organisations, voluntary or statutory, to enforce them. They do exist and are operative in a large majority of the profession, but the question raised in the Congress is, How are we to deal with those who have little or no sense of such principles and how shall the profession be protected from those members of it who are blind to the way of honour and who put their own individual interests above the dignity and interest of the profession? The answer to this question is twofold. First, we must make sure that all medical men know their duty to their profession; and secondly, we must find some means of gently compelling them to do it. It was amply recognised at the Congress that many erring members err from want of knowledge and of thought. There is no adequate teaching of medical morals either in the books or in the schools of medicine. They are taken for granted. Several speakers urged that the subject should be dealt with and taught in the medical schools; others that it should be more fully discussed in books. But there was a general agreement that in all countries and localities there should be an organisation charged with the defining of medical duty in relation to difficult circumstances or new questions. In regard to ethical matters the opinion of men of repute in the profession on questions of conduct has a certain weight, on the strength of which penal or disciplinary measures may properly be taken. The General Medical Council acts on this principle in Great Britain, and its action has been amply supported by courts of law. In Austria and Germany, as we have seen, Chambers have been established by law having, in cases of misconduct, power to fine, or even to take away the right of practice. But it is obvious that such extreme powers must be reserved for extreme offences and that short of such offences voluntary and persuasive means of remonstrance must be chiefly relied on. Even in autocratic Austria Dr. ADLER showed that the powers of the Medical Chamber are not absolute but are controlled by the local government authorities, which may rescind the action of the Chamber when it goes too far.

Dr. DE GOUVÉA of Rio Janeiro showed that medical ethics were at a low ebb in that beautiful capital till the formation of a medical society in the city. This produced good effects which led to the formation of other societies throughout Brazil. Dr. ERNEST JENDRASSIK of Budapest gave a most encouraging account of the work of a medical union which Hungarian practitioners have formed, preferring this to the Medical Chambers created by law in Germany and Austria. It has collected statistics and is seeking to fix minimum fees for insurance work and for medical contract work; it has also established a benefit fund, but its fundamental purpose is to abolish "undercutting." Dr. HANSSON of Christiania showed that the Norwegian Medical Association had dealt with the question of sick club practice, and had laid down the principle that the post of medical officer was not to be accepted unless with the consent of the local branch of the Association. Such reports as these from different parts of the world, while they testify to the value of the Congress, show the variety of opinion prevailing and the need for patience and breadth of judgment. The time has not yet come for an international code of medical ethics. The proposal for a committee to draw up such a code did not take definite form but remained as a pious wish. None the less the Congress has done and will do great good by

PAGE NOT AVAILABLE

Finland, it is true, as the result of the legislature enabling the compulsory examination and treatment in hospital of suspected individuals, syphilis has much diminished in the course of 20 years; congenital syphilis has become less frequent, and both the hereditary and acquired forms of syphilis have become of much milder type. Finland is not Great Britain, and public opinion is not with us ripe for legislation on this point.

Some of the factors in the production of insanity are capable of being dealt with by way of restriction or prevention. The ravages of alcoholism, the contagion of tuberculosis—a known and potent cause of idiocy and imbecility in the offspring of affected parents—and the marriage of congenital imbeciles, chronic epileptics, and persons who have had one or more attacks of insanity, all these offer themselves for the application of preventive measures. The free and unchecked production and propagation of the lunatic, the idiot, the imbecile, and the neuropath constitute a serious and growing danger to the safety of society, a menace to its public health, and a burden to its resources.

A REPORT upon the condition of the London burial-grounds[1] which the London County Council has just issued deserves more than passing notice from us, for it deals in a practical way with a subject of great concern to the public health, one that is more than any other surrounded by feelings of religious sentiment. The report consists in the main of an excellent account by Dr. C. W. F. YOUNG of burial-grounds in which the London dead are interred, and of an introductory statement by Mr. SHIRLEY MURPHY, who indicates the conclusions at which he has arrived and the course which he thinks should be adopted with a view to bring the method of disposal of the dead into better harmony with health requirements. The report is the outcome of a resolution (adopted by the London County Council at the instance of Mr. SHAW-LEFEVRE) that inquiry should be made as to the condition of the burial-grounds chiefly used by the population of the County of London, as to whether further provision for burial is required, and whether further regulation is necessary in the interests of public health and decency. The information, therefore, which the report supplies is directed to answer these questions. So far as quantity of accommodation for the London dead in existing burial-grounds is concerned it does not suggest any doubt that for the immediate present there is ample provision; but it does indicate, and that very definitely, that the instruction of the London County Council has come none too early. The representatives of London on its County Council, as well as in the Imperial Parliament, should take into serious consideration without undue loss of time the course to be adopted for the disposal of the 100,000 corpses and more which annually have to be provided with resting-places.

The whole trend of the report is towards one conclusion. The inhabitants of London must determine whether the system of interment which is to be practised in the future is to aim at the preservation of the dead as in the past or at the speedy dissolution of all human remains. Upon this question the medical officer of health of the County of London has no doubt. His verdict is that every opportunity should be given for speedy dissolution, and he holds that no new brick graves and no new vaults should be provided in London. Beyond this he points out the advantages that would result from some local representative body having the power to make regulations which could be strengthened from time to time and which would determine the conditions under which interment should be carried out. Public opinion is evidently, as the report shows, moving in the desired direction, but it moves slowly. The wish to preserve as long as possible the remains of those who in life have been loved governs the usual method of interment, while inseparable from this sentiment is the interest of the undertaker. Neither change in sentiment nor change in practice can be suddenly effected, but change would be more speedily brought about if there were guidance by regulations made by those who are in touch with popular feeling and if trade interests could be eliminated by the vesting of all burial-grounds in public ownership. The teaching of Sir SEYMOUR HADEN and of Dr. VIVIAN POORE cannot longer be disregarded. Their work, and especially that of Sir SEYMOUR HADEN, has shown how speedily the earth does its duty when man does not by artificial methods prevent nature from accomplishing her final object, the resolution of organic matter into its ultimate elements. The question which remains is how this teaching can be adopted in the disposal of thousands of human bodies with due regard for the feelings of the survivors and with due regard to the conditions existing in centres of population.

The report points out the unsuitability of clay soil for the purpose of burial, and Dr. YOUNG discusses fully the results obtained under different conditions. Mr. SHIRLEY MURPHY hesitates to accept surface burial as a practical solution of the difficulty without more experience, but he definitely indicates the need for the experiment of surface burial to be made under proper conditions. There should be some opportunity for this to be done soon, inasmuch as the control of burial-grounds has been transferred by Parliament during the present session from the Home Office to the Local Government Board, showing that the matter is intended henceforth to be considered especially in its sanitary relations. The report published by the London County Council sets out the issues well and we are interested in the manner in which it will be received. At a later date we shall discuss in more detail the various questions which it raises.

[1] Sanitary Condition of Cemeteries and Burial-grounds: A report by the medical officer of health presenting a report by Dr. C. W. F. Young, assistant medical officer of health, as to the condition of the cemeteries and burial-grounds chiefly used by the population of the County of London, as to whether further provision for burial is required, and whether further regulation is necessary in the interest of public health and decency. London: P. S. King and Son.

Annotations.

"Ne quid nimis."

THE POSITION AT THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

WE publish in another column a further communication from the medical staff of the National Hospital for the Paralysed and Epileptic, Queen-square, and we share with them the surprise which they express in their opening sentence. Apparently to-day (Saturday, August 11th) has been fixed by the board of management for an official

symptoms, fatigue, disinclination for work, emaciation, and nervous irritability and depression. The patient shown to the society corresponded completely to the type described by M. Hayem. She was a woman, aged 53 years, who had been treated for chlorosis since the age of 23 years and was subject since the age of 25 years to disseminated and erratic pains which corresponded to the clinical type of general neuralgia of Valleix or painful neurasthenia. For 18 months she had suffered from obstinate dyspepsia with furred tongue, fœtid breath, epigastric pains, constipation, and sometimes glairy stools. For three months there had been a yellow tint of the skin without biliary colouration of the conjunctiva or urine. The tint was of a chamois-leather colour, especially marked on the face, hands, along the crests of the tibiæ, and on the soles. It suggested xanthodermia rather than icterus. The mucous membranes were not coloured and the urine, which was examined on several occasions, never showed a trace of bile pigment. This was in favour of the diagnosis of xanthodermia but the presence of biliary pigment in the blood serum settled the question. Blood obtained by cupping was examined after the retraction of the clot. The transuded serum was of a light mahogany colour; it darkened all the spectrum from blue to violet and gave Gmelin's reaction. After the appearance of the discolouration of the skin the patient wasted, the constipation became more marked than ever, and the neurasthenia increased. Examination of the internal organs was negative; the liver was not enlarged and the fæces were neither bilious nor discoloured. The urine contained neither sugar nor albumin; it amounted to from 1000 to 1200 grammes in the 24 hours, was of specific gravity 1013, and contained about 15 grammes of urea. This oliguria was no doubt in relation with the dyspepsia, for the renal permeability was normal. The pathogenesis of *ictère acholurique* was disputed. MM. Gilbert and Castaigne thought that the acholuria was due, at least usually, to defect of renal permeability; but this case was opposed to that hypothesis. M. Hayem supposed that there was a slight infection of the biliary passages and too little bile pigment in the blood to pass the renal filter. In the present case the icteric tint diminished 10 days after the administration of sulphate of soda, in daily doses of 75 grains, which regulated the bowels.

THE WATER-SUPPLY OF THE CITY OF LONDON

MORE than half a century ago Mr. (now Sir) John Simon, who was at the time medical officer of health to the City of London, strongly urged in his annual report that the supply of water for domestic use should be constantly instead of intermittently given. We regret to see that Dr. Sedgwick Saunders, the present medical officer of health to the City, in a report which has recently been issued, still finds cause to complain that the East London Waterworks Company has failed to carry out the statutory requirements which have been made that the water consumers in its district shall receive a constant service.

"In October, 1898," Dr. Sedgwick Saunders says, "I reported upon the absence of domestic cisterns in 89 houses at the following places—viz.: 29 in Bishopsgate-street Without, eight in Brushfield-street, four in George and Catherine Wheel-alley, one in Great Alie-street, two in Little Somerset-court, 20 in Mansell-street, 14 in Montague-court, 10 in Mason's-court, and one in Spital-yard.

The necessity for this provision arose from a scarcity of the water derived from the East London Water Company during the exceptionally dry summer season, the supply being only furnished for a limited time at certain periods of the day. The want of these receptacles for storing water occasioned much suffering in the poorer districts, owing to its intermittent delivery.

The Sanitary Committee at once recognised the importance of seeking action, and under the powers conferred upon them by the City of London Sewers Acts, 1848, 1851, gave an order that in all the above-mentioned dwellings cisterns should be erected without delay.

After much negotiation the owners of 59 houses supplied the deficiency without coercion, but in 18 instances it was not until pressure was put upon unwilling landlords by the issuing of 'compulsory' orders that this was effected. In five cases, however, the owners proved obstinate, and the Public Health Department was driven to the only alternative of ordering the works to be executed by its contractors, and in due course the defaulters will be sued for the cost thereof, as the law provides.

The question of doing away with cisterns in domiciles has exercised the minds of owners of house property and others, who argue that a 'constant service' ensures a purer supply of water; and so it certainly does when cisterns are improperly placed under inaccessible roofs or beneath floors without efficient protection from weather, dust, droppings of animals, or other sources of pollution; but if they are constructed in positions where they can be easily inspected and frequently cleansed we may concede the point, but it is only the commonest of common sense to insist upon some relief from the tyranny of the water companies, who, whilst charging the maximum of tax justified by inequitable legislation, give in return the minimum of accommodation in periods of water famine or when any accidental disruption occurs in their mains or other mechanical appliances; in other words, when the so-called 'constant service' becomes irregular.

What is the tenant to do under this contingency? The poor have neither the means nor the leisure to collect and store water for use during the intermissions of supply, and to them the want of water entails an amount of discomfort and uncleanliness that emphasises the bitterness of want and misery."

We do not propose to discuss in detail the various points raised by the paragraphs we have quoted from Dr. Sedgwick Saunders's report, but they naturally suggest one or two questions which are worthy of consideration. When a constant supply of water is given there is no need for cisterns, and water drawn straight from the mains is preferable for all domestic purposes. Under the present statutory regulations, as readers of THE LANCET know, all the London water companies are required to give constant service. This being the case, is it fair that the owner of a house in London should be out of pocket because a water company fails to perform its statutory duty? If a cistern be rendered necessary by the default of a water company, would it not be right that the cost of the cistern should be paid by that defaulting company? A metropolitan water company which fails to give constant service renders itself liable to heavy fines which can be inflicted at the instance of a metropolitan authority. Has the Corporation of London made any attempt to bring this moral pressure to bear on the East London Waterworks Company for its defaults? And if not, why not? Dr. Sedgwick Saunders gives no information on this subject. The City of London is chiefly supplied with water by the New River Company, to which Dr. Sedgwick Saunders in his report, no doubt inadvertently, does a considerable injustice by omitting to differentiate it from the "companies who, whilst charging the maximum of tax justified by inequitable legislation (i.e., charging the price settled by Parliament), give in return the minimum of accommodation." It is but simple justice to point out that the New River Company does not exact the maximum water-rents to which it is entitled, a fact which was clearly pointed out and duly emphasized by the City Remembrancer in the evidence which he lately gave before Lord Llandaff's Commission.

CYSTS IN THE ABDOMINAL WALL STRUCTURALLY IDENTICAL WITH OVARIAN CYSTS.

IN the *Boston Medical and Surgical Journal* of July 12th Dr. John Homans describes this curious and rare condition. When operating on a very old-standing enormous adherent ovarian cyst weighing 102 lb. he was surprised to find a large cyst in the abdominal wall in the epigastric region

authority, the matron may possess has been accorded her by act of grace; she can claim nothing as her bounden right."

The latter portion of Miss Julian's remarks is worded too strongly. All positions in life are what we make them, but we think that in the small workhouse infirmary the care of the sick and the provision for nursing should be vested in the general practitioner who is medical officer to the workhouse, but in the large parish infirmary responsibility with regard to the nursing staff, except as regards purely medical duties, should be, as is the case in any general hospital, vested in the matron or superintendent nurse. In country workhouses the position of the superintendent nurses should be made more independent of the master and matron and more dependent on the medical officer. Miss Julian thinks that the great parish hospitals should be taken over by the State and freed from the union brand and the workhouse taint. So long, she says, as workhouse nurses are regarded as being on a lower plane than those attached to voluntary hospitals so long will the sick poor in rate-supported institutions lack a full measure of skilled attention. There are no doubt difficulties in the way, but until some arrangement is made for separating the deserving poor from the class who never do any work and do not wish to work so long will the workhouse be looked upon as a disgrace instead of a refuge.

THE HOUSING OF THE WORKING CLASSES.

AN interesting conference was held in London on the last two days of July upon the problems arising out of the overcrowded condition of great cities and the various efforts which have been made to deal with them. Sir Sydney Waterlow and Mr. R. M. Beachcroft, L.C.C., were chairmen of the two meetings held and various other gentlemen whose knowledge and experience qualified them to do so read papers and expressed their views, the general tenor of which might be said to be that whereas the rehousing of the class earning regular and substantial wages presented comparatively little difficulty and gave satisfactory results the question of how to provide wholesome dwellings in which members of the strata below these could and would live had hardly yet been solved. In addition to this there seemed to be a considerable weight of opinion adverse to the provisions already made by Parliament to enable local authorities and individuals to deal with the evils of overcrowding and to replace it by a better state of things, the necessity for the coöperation of individual effort being fully recognised. A resolution was passed that "the conference is of opinion that the present method of dealing with insanitary areas is extravagant and unsatisfactory and urges Parliament to provide some less expensive and more expeditious mode of procedure." It is certainly beyond question that legal processes in the United Kingdom are, as a rule, both cumbrous and costly, but at the same time the powers given under the Housing of the Working-classes Act will strike many as considerable and of such a nature that it should be impossible for them to be hastily employed or for the liabilities which they imply to be undertaken without due consideration.

THE STUDY OF INEBRIETY.

THE Society for the Study of Inebriety has appointed a committee of medical men to inquire into the relation of heredity to the production of inebriety. The president is Dr. Wynn Westcott, coroner for North-East London, and the committee includes such well-known names as Mr. Victor Horsley, Dr. Sims Woodhead, Dr. Archdall Reid, Dr. Heywood Smith, Dr. Harry Campbell, with Dr. Thomas Morton as secretary. Much progress has been made with the investigation, and the medical profession is now asked to supply evidence on the following important subject: "The committee are fully satisfied that drunken parents tend to have children who become drunkards, but they earnestly desire to obtain evidence bearing upon the question whether a parent who himself inherits *no* special tendency to inebriety can, as the result of mere intemperate habits, entail upon his children a potential inebriety." Communications will be gratefully received by the president or secretary, and may be addressed to 396, Camden-road, London, N.

THE LAMBETH WATERWORKS COMPANY.

A CORRESPONDENT complains in the *Times* that the Lambeth Waterworks Company has again lately failed to give a constant water service. Each metropolitan vestry and each individual water-rent payer now has power to punish a defaulting water company. It appears that the public spirit and energy which animated Mr. Archibald Dobbs do not co-exist in the district of the Lambeth Waterworks Company. It may be safely predicted that the full statutory fine inflicted on a peccant water company would be more effective than any number of letters to the newspapers. And the Courts are open.

THE LATE DEBATE ON THE SOUTH AFRICAN COMMISSION.

IN the debate on the second reading of the Appropriation Bill a very lively encounter took place between Mr. Burdett-Coutts and Mr. Balfour. Mr. Burdett-Coutts attacked the South African Commission in strong terms. He contended that it was divested of all the power requisite to get at the truth, that witnesses would be afraid to give evidence before it lest they should injure their future prospects, and he appealed to Mr. Balfour to take a more serious and sympathetic view of the question than the Government had hitherto done. Mr. Balfour, who has throughout spoken with a certain degree of asperity, which is quite unusual with him, in connexion with this subject, replied to Mr. Burdett-Coutts and indignantly repudiated the correctness of such statements and the inferences which might naturally be drawn from them. For our part we can only regret the manifestation of any irritation or contentious spirit in the matter. We are quite content to leave the inquiry in the hands of the Commissioners in the full assurance that if Lord Justice Romer requires any further powers to strengthen his hands in the investigation over which he presides or considers that anything further is required to protect and safeguard the witnesses he will lose no time in representing what is either requisite or expedient. What everybody desires is that the inquiry should be thorough—that the whole truth should be elicited and boldly stated without favour or affection to anyone. The precautions which have been taken seem to us sufficient to impart assurance to the most timid and we cannot believe that under such circumstances any witness will shirk a duty which he owes alike to his conscience and his comrades, any more than we can believe that the members of the Commission will fail to conduct the investigation throughout with absolute impartiality. If Mr. Burdett-Coutts really desires that the whole truth should be elicited he cannot perform a greater service, we think, than by writing to his correspondents in the spirit we have indicated. Mr. Balfour towards the end of the debate made the important statement that the Government had decided on appointing the Commission before Mr. Burdett-Coutts had brought forward his charges. At the conclusion of the campaign—as everybody foresees and the Government is pledged to do—an exhaustive inquiry into the whole conduct of the war in South Africa must inevitably take

place. The Commission now sitting is only part, and a very limited part, of a big subject.

THE OPEN-AIR TREATMENT OF PHTHISIS FOR THE POOR.

A MOVEMENT is on foot for providing for the poor of the metropolis a hospital for the reception of phthisical patients in which to carry on the open-air treatment. The movement originated with the board of management of the Poplar and Stepney Sick Asylum District. The managers doubtless thought that what was so essential in the case of the rich was still more so in the case of the poor whose power of resistance and recuperation is apt to become fatally impaired at an early period of tuberculous disease. It was found on inquiry that in this particular district alone there had been 65 cases of phthisis which might have been saved by this treatment. Accordingly the managers called together the medical officers and clerks of the unions comprised in the district. After this they sent a deputation to the Local Government Board on the subject. The Board expressed full sympathy with the views of the managers. The Board at the same time have suggested that the guardians of districts should not act seperately, but that such a provision should be made for the metropolis as a whole and that the management of it should be under the control of a metropolitan authority. They further suggested that the managers should invite a conference of the representatives of each Poor-law authority in the metropolis on the subject and have further communication thereafter with the Local Government Board. We highly approve the object and learn with gratification that the board of management of the Poplar and Stepney District have sent to each board of guardians in the metropolitan district a circular inviting a conference. It is desirable that every board should send a representative in sympathy with the object and with power to support the furtherance of it. We are not quite so sure that one huge institution for the whole metropolis is desirable or that this should be labeled a hospital. The congregation of too many such cases is depressing, and the name of sanatorium or convalescent home is to be encouraged rather than that of hospital. These are details. But as to the main object there can be no difference of opinion, and without advocating extravagance the institute should be pleasantly situated and generously administered with a view to the comfort and cheer of the patients.

THE Colonial Office has received a telegram to the effect that during the month ended August 2nd there were 10 cases of plague in Mauritius all of which proved fatal.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Famine: latest Mortality Returns.—The Plague.—Breeding-grounds of Anopheles in Calcutta City.—Sickness and Mortality in India.

THERE are still about five millions of people under relief and the mortality in the famine districts is very high. Cholera is the chief cause of death. At Ajmere-Merwara during June the death-rate was 180 per 1000 and in Bewar 144 per 1000 per annum. The worst districts were those of the Panch Mahals and Khandesh, inhabited by the Bhils and other forest and low caste tribes, where a death-rate of 256 per 1000 per annum was recorded. In Dhandesh cholera alone accounted for 63 per 1000 out of a rate of 150. Other districts in the Bombay Presidency were also severely affected. No returns are available for the native States but the terrible mortality amongst those who are crowding over the border into British districts tells its own tale. With all this terrible distress the prospects of the monsoon are very disheartening. Almost the whole of the famine tracts and North-Western India are still rainless.

The plague continues everywhere to decrease. Last week the number of fatal cases in the whole of India was only 227, Calcutta returning 107, Bombay City 62, Bengal Presidency 28, and Bombay Presidency 11. Only one case was reported at Aden.

The report of the chairman of the Calcutta Corporation has just been published. In it he directs attention to the plague measures during the past year and states that entire reliance was placed upon disinfection. He says that the change of policy has been justified by the result. "Not only were the people generally more pacific but information was obtained much more freely of plague cases." The difference between the normal and actual mortality is accounted for by the number of plague and suspicious cases registered. In addition to disinfection of the room where the plague patient was found attempts have been made to disinfect adjoining rooms and with some success. As I have before reported the system adopted seems to obtain information of nearly all the cases of plague which have occurred, notwithstanding that considerably less than half of the cases are seen by responsible authorities during life. The number of deaths from small-pox and cholera were both less than the average.

Experiments have been made by the health officer and his assistants in Calcutta during the past four months on the breeding-grounds of anopheles. The larvæ have been found in a large number of places, especially in small tanks containing rather foul water and low forms of vegetation. They were not generally found in the filthiest tanks containing sewage or in drains. The most favourite breeding-ground seemed to be excavations in the ground containing water. The water on paddy fields did not contain them, nor were they found in wells. There was great difficulty in exterminating them from tanks containing much vegetation, but other pools were easily covered with kerosine.

The annual report of the Sanitary Commissioner with the Government of India has been recently issued and like the immediately preceding volumes is much more than a mere compilation of statistics and local reports. Many parts of it prove very interesting reading. It deals as usual with the health of the British and native armies, with the vital statistics of the general population, with vaccination, and with various sanitary works. The mortality in the British army in 1898 was 20·05 per 1000, as compared with 22·93 for the previous year and as compared with 13·33 for the native army. Of this amount no less than 10·17 was due to enteric fever, which thus constitutes 51 per cent. of the total deaths and is unfortunately still on the increase. Hepatic abscess caused 8 per cent., heat-stroke 6 per cent., and dysentery 4 per cent. Amongst many civilian officers there is a tendency to put down to heat-stroke cases which cannot be easily differentiated from the "anomalous" fevers and the same tendency seems to exist on the military side. The heading of "heat-stroke" doubtless includes many cases of fever which have little or nothing to do with the heat at all. The sickness in the British army is chiefly caused by ague and venereal diseases, the former causing 27 per cent. of the total sickness, the latter 25 per cent. It is interesting to note that in the native army ague caused no less than 41 per cent. of the admissions. Compared with former years cholera has markedly declined. There were no less than 689 deaths from enteric fever, and the average number of men constantly sick from this one disease was 321, while other fevers were very small in amount. It is said that the British army is at present a youthful army, with 90 per cent. of the men under 30 years of age, whereas the corresponding percentage in 1871–79 was only 67. The figures for age and length of residence repeat former reports in the dangers to young soldiers and new-comers. It is satisfactory to find that the admission rate for venereal diseases has much improved, but this is explained partly by the widespread adoption of treating the affected men as out-patients. The death-rate among officers in the British army was 16·26 per 1000 and among those in the Indian army it was 10·18, both rates being much lower than in the preceding year. In the native army the chief causes of death were pneumonia and remittent fever, while the chief cause of admissions to hospital was ague. What "remittent fever" means is not very

clear; the title seems to cover a multitude of difficult diagnoses. Native troops suffer but slightly from enteric fever, and the death-rate from this cause is put down at only 0·13 per 1000, and forms only 1·2 per cent. of deaths, as compared with 50·7 per cent. amongst British troops. Natives are more liable to ague and so-called remittent fever, and apparently much less often attacked with "simple continued fever." Taking these statistics as a whole, it may be concluded that were it not for the prevalence of enteric fever among the British the actual liability to "fevers" would be greater amongst the native troops. With regard to venereal disease, there were only 40 admissions per 1000 men among native troops, against 363 for every 1000 among British troops. The Gurkhas, as usual, suffered proportionally more than other native troops.

July 5th.

PLAGUE IN AUSTRALIA.

(FROM A SPECIAL CORRESPONDENT.)

THE returns of plague in Sydney for the week ending June 23rd are as follows: Remaining at the beginning of the week, 76; admitted, six; discharged 14; died, none; remaining at the end of the week, 68. The totals up to the end of the week are as follows: Cases, 284; deaths, 98; discharges, 118; "contacts" isolated, 1586; "contacts" remaining, 91; cases among "contacts," seven. The above figures include Chinese, of whom 10 were admitted, with eight deaths, all the other patients being whites.

June 26th.

The returns of plague in Sydney for the week ending June 30th are as follows: Remaining at the beginning of the week, 68; admitted, 12; discharged, 14; died, three; remaining at the end of the week, 63. The totals up to the end of the week are as follows: Cases, 296; discharged, 132; died, 101; "contacts" isolated, 1686; "contacts" remaining, 111; cases among "contacts," seven. The above figures include Chinese, of whom 10 were admitted, with eight deaths, all the other patients being whites.

The larger number of cases admitted during the week came from localities still more widely scattered than during recent previous weeks; and, as time goes on, it becomes more and more difficult to trace them to dwellings within areas known, or on good grounds presumed, to be infected—that is, by harbour-infected rats. On the other hand, no probable source of infection for them can be fixed upon; these cases are as little connected with each other as (with few exceptions) have been all those which preceded them. Personal communication between infected and clean families clearly has been no factor in the rise and maintenance of this epidemic at Sydney.

Nevertheless, rats are not the sole possible source of the disease; here as elsewhere plague appears to have been contracted under circumstances which excluded diseased rats, though only in a single instance. The quarantine ground may be described as having been divided into three parts: one contains the hospital, one the convalescent quarters, and the third the "contact" camp. The two former are fenced and "contacts" and staff are alike prevented from entering; however, while the hospital fence secures a true isolation, the convalescent fence is only designed to prevent mingling of "contacts" and convalescents. But there is an exception: a scavenger enters the convalescent enclosure during the night only—at times, that is to say, when the convalescents are in their beds. It should be further noted that convalescents are treated as such only when they would be fit for release but that their buboes continue to discharge. This scavenger fell ill of plague after having performed similar duties for about six months. He was a young man in perfectly good health and was the only member of either staff, permanent or temporary, who had escaped inoculation—probably because he was already at work when the plague began, having been originally engaged in connexion with small-pox. On his right hand he had six unhealed, but not quite recent, grazes, of which one was slightly inflamed, and on the fore finger of the same hand he had several cracks or chaps on its external surface which ran horizontally to its anterior surface. His buboes were axillary and cervical on the right side. Bacteriological examination of liquid got from some of the scabs revealed no bacilli, nor were any present in serum drawn from a bubo; but this was taken two days after Yersin serum had been administered and after his temperature had fallen. His attack was slight. Notwithstanding the negative result of the bacteriological examination there was no room for doubt that his disease was plague in the opinion of those best able to judge. After a quite exhaustive inquiry into the conditions under which this man lived and worked at the quarantine ground (which he had not left during the long term mentioned) it seemed most likely that he had become inoculated in the right hand from dressings discarded by the convalescents; yet none of them reached the convalescent wards until long after the time when, according to the best information, bacilli have disappeared from the pus discharged from open buboes.

One other observation noted during the past four weeks is interesting. It has already been remarked that neither minor nor ambulant cases accompanied the beginning of this epidemic nor occurred during the greater part of its course. The first case recorded was the first case which occurred, and it was mild. The next, which happened just a month later, was fatal and it was immediately followed by many others among which the death-rate was high. After that the epidemic continued for many weeks with a steady virulence or intensity which yielded on an average a fatality of about 33 per cent. among whites. Lastly, the term now set in commenced; two or three cases were discovered almost by accident and were of the class known as ambulant. But besides this the virulence of the infection manifestly declined so that nearly all the new cases were of little apparent gravity. Recalling for a moment the fact so often pointed out already—namely, that the epidemic has certainly not been maintained by communication of the disease from person to person (whatever the few exceptions may have been)—it appears that both the primary virulence of the poison and its subsequent enfeeblement must have been independent of the agency or intervention of the human body. That the first case of all was slight may be nothing to the purpose; yet there is no evident reason why it should have been so were the virus derived from the same source as that with which the second, quickly fatal, case was infected. However, it was an example of inoculation by the flea, and it had shown the bleb which is said to be wanting when the implanted virus is very active. But, as regards manifestation in man, it is quite plain that there was no gradual exaltation of virulence of the infection by repeated passages through the human body (the possibility of this being assumed), nor can it be argued plausibly from the facts that the decline of virulence, now become apparent, has been the consequence of similar passages. The fact begins to appear that the whole process went on quite independent of man, who merely suffered incidentally and who was not of importance to the maintenance and diffusion of the disease. This statement, in my opinion, might have been expressed in more general terms. At all events, for the future the possibility of infection by rats and the subordinate possibility of infection by fleas must be excluded before other modes of infection need be seriously discussed.

July 3rd.

TOTNES HOSPITAL.—The annual meeting of this institution was held on July 30th. The report showed that 45 in-patients had been admitted during the year and that there was a favourable balance of £56 remaining. The committee stated that satisfactory progress has been made with the building of the new hospital. The Duke of Somerset was elected patron and Mr. A. M. Singer was elected president.

VACCINATION FEES.—The Vaccination Committee of the Cardiff Board of Guardians at their meeting on August 3rd decided to recommend the guardians to approach the Local Government Board with a view to the reduction of the minimum fees of the public vaccinators. It was stated that during the first year which has elapsed since the passing of the new Act 3743 vaccinations had been performed, the fees of the public vaccinators amounting to £1209. The year previous to the passing of the Act 5770 vaccinations had been performed, for which the public vaccinators had received £392 in fees.—At the meeting of the St. Germans Board of Guardians, held on August 2nd, it was stated that the cost of vaccination for the years ended March, 1898, 1899, and 1900, amounted to £23, £30, and £133 respectively.

THE THIRTEENTH INTERNATIONAL CONGRESS OF MEDICINE,

HELD AT PARIS, AUGUST 2ND—9TH, 1900.

THE Thirteenth International Congress of Medicine was opened in Paris on Thursday, August 2nd, under the patronage of the French Republic. The arrangements of the Congress have been made by the Government Department of Congress and the President of the Congress is M. Lannelongue. M. Odilon Marc Lannelongue is Professor of Surgical Pathology in the Faculty of Medicine of Paris and Surgeon to the Hôpital des Enfants Malades. He was enrolled an Honorary Fellow of the Royal College of Surgeons of England at the recent centenary of the College.

The following are the Executive Committee:—President: M. Lannelongue. Secretary-General: M. Chauffard. Treasurer: M. Duflocq. Members: M. Bouchard, M. Bouilly, M. Brouardel, M. Dieu, M. Gariel, M. Le Dentu, M. Malassez, M. Nocard, M. Raymond, M. Rendu, and M. Roux. Secretaries: M. de Massary and M. Léon Weber.

The first outward and visible sign of the thousands of medical men attending the Thirteenth International Congress of Medicine was seen on the morning of the last day of July when the Rue de l'École de Médecine was blocked by cabs containing medical men from all parts of the world anxious to go through the formalities which were necessary for official acceptance as members. Though nothing authoritative was given out and the tickets for the different fêtes and entertainments were duly distributed there was a very general opinion quite early that the sad end of King Humbert of Italy would mean the abandonment of the official receptions. This sombre beginning of the Congress was not relieved by the monotonous proceedings at the first general meeting held in the Salle des Fêtes. Most of those who attended this dreary function found their way into the grounds of the Exhibition and in the brilliant sunshine of that Thursday afternoon the Exhibition certainly was a revelation of what can be done by the French in building substantial stone edifices which at once attract attention and demand admiration by reason of their exceeding elegance and beauty. Properly to appreciate the brilliant architectural *tour de force* achieved the spectator should proceed in one of the swift passenger steamers plying on the Seine from the Pont d'Iéna to the Pont Alexandre III. Both banks of the river between these points are lined by veritable palaces of glistening white stone, affording a spectacle well exemplifying the French capacity to rise above criticism in matters of taste. But this is not the place to attempt a description of the Exhibition.

Some little disappointment has been expressed at the small attendance from Great Britain. This is attributable to many causes, but most certainly the general idea that there would not be sufficient hotel accommodation was fallacious, for suitable lodging and good food at reasonable prices, considering the circumstances, are to be had without undue difficulty. The suspicion that the reception of the English would not be of the warmest has been signally disproved by the hearty welcome accorded to them. Certainly the impression prevailing at the Hôtel Trocadéro, where many of the British section, including Sir William Mac Cormac, Sir T. Lauder Brunton, Sir J. Burdon Sanderson, Sir Felix Semon, and Sir Dyce Duckworth, are staying, is that their reception has been most cordial and sincere. On arriving in Paris the first place to go to was the École de Médecine where, in the roomy corridors round a refreshingly cool-looking fountain set in a shrubbery under shady trees, the members of the Congress found officials for the different nationalities waiting to distribute the insignia denoting membership and to impart information to strangers from every country. It was here that the paucity in numbers of the British section was most forcibly demonstrated, for the two or three individuals gathered at the part devoted to Great Britain contrasted strongly with the crowds surging round the Russian and German sections. After receiving the official card of entry to the Exhibition most members repaired across the road to the Faculté de Médecine, where the ladies' committee inscribed the names and addresses of members' wives and daughters and entertained the lady visitors in a sumptuously furnished room forming a pleasant haven of rest.

THE POSTPONEMENT OF FESTIVITIES.

A little while ago fears were entertained that one or more of the four medical congresses would suffer in consequence of international mourning. It was then thought that in the event of official confirmation being received of the massacre of the ambassadors and other Europeans at Peking many of the official entertainments would be postponed. There was no established etiquette compelling such a course because, fortunately, the wholesale massacre of ambassadors was a disaster so unprecedented that the framers of even the most elaborate protocols had never foreseen such an occurrence; still, it was hardly likely that illuminations, music, and dancing would be organised by a Government on the morrow of such a disaster, and therefore it was widely rumoured and believed that many of the proposed festivities would not take place. This anticipation has been realised, and this at the very time when it was thought most likely to occur, but its cause was totally unexpected. It is not for the ambassadors and Europeans at Peking that all the Courts are in mourning—for however precarious their situation it would seem that for them there is still hope—but for the King of Italy. A fortnight ago the general secretary of the International Congress of Hygiene, Dr. A. J. Martin, was discussing this matter and he remarked that he hoped that the mourning for the victims of the Boxers would be over by August 10th when that Congress begins. This hope will presumedly be realised. What was expected has happened and yet the cause is utterly different and altogether unexpected. So many of the projected entertainments have been postponed which, at least for those who are remaining for but a short time in Paris, is equivalent to being totally abandoned. On Tuesday, July 31st, the members of the International Congress of Deontology and of the Medical Press Congress were to have been entertained at a grand fête at the Hôtel de Ville. This was postponed at the last hour. On August 5th the members of these Congresses, together with those of the Thirteenth Medical Congress, were to have been received by the President of the Republic, M. Loubet, at a garden party at the Elysée. This has likewise been abandoned, and other official receptions will probably share the same fate. No doubt the congresses will achieve their respective missions, but the more cheerful side of these gatherings has been sadly clouded over.

THE BANQUET TO LORD LISTER.

It is generally agreed, however, that public sorrow and mourning must not interfere with the private hospitality shown to the foreign visitors and guests. Therefore the private banquet organised in honour of Lord Lister by Professor Charles Richet and the Scientia society was not put off. At the Restaurant of the Congresses, opposite the Congress Hall in the Exhibition grounds, the leading professors of the Faculty of Medicine and some foreign members of the Congress of the Medical Press and the Deontological Congress met on Wednesday, August 1st, to welcome Lord Lister. It was a very quiet gathering of thoughtful earnest, and learned men who had all made their mark in the world of science and who all profoundly admired Lord Lister's career and work. At dessert Professor CHARLES RICHET was the first to rise and tender his thanks to Lord Lister for having come "to receive the homage of our

admiration." Throughout the world there was no surgeon who was not deeply indebted to Lord Lister and there was no physician who did not feel equally indebted to Pasteur. These two names would illuminate their century; their names would live throughout posterity. When a man by his genius had saved thousands and thousands from untold suffering he deserved more than their admiration—he was entitled to their love and gratitude. If all who had benefited from Lister's work were there, even the great Exhibition itself would not be large enough to hold the assembly.

Dr. BOUCHARD spoke next and recalled how some 17 years ago, when Lord Lister appeared before the Congress then meeting at Amsterdam, an immense acclamation arose, especially from the Dutch. After Lord Lister himself those who were most astonished by this ovation were the English and the French members present. Lord Lister was not then a prophet in his own country, and yet had ever a discovery been so quickly acknowledged? A hundred years after Harvey scientists were still discussing whether the theory of the circulation of the blood was true. This century commenced in the noise of battle and civil discord and yet in the midst of this trouble a man came and endowed the world with the benefits of vaccination. The century ended with the curse of war and the shame of abominable assassinations and then, said Dr. Bouchard, "you come and show us how to heal wounds. We wish in the name of the suffering peoples of the whole world to honour you as our great benefactor."—Professor GUYON spoke in the name of the Faculty of Medicine and Dr. LUCAS CHAMPIONNIÈRE related how 32 years ago he had heard Lord Lister explain his theories. He was then the object of hostile criticism and yet how rich with new developments and possibilities had he rendered the intervening time. "You acquired the conviction that there was no spontaneous generation; why, then, should it exist in surgery? That was your new faith, and when I repeated this in France I was called the apostle of a new religion; and I have merited this title by reason of my faithfulness to your teaching. ..... All new discoveries of the 30 years are your tributaries; none of them would have been possible but for you. We can remember the miserable condition of surgery and how great was the mortality. Nélaton said that a statue in gold should be raised to the person who was able to prevent what we now know as 'sepsis.' You have deserved that statue and our only regret is that at present we cannot offer it to you."—Dr. PINARD spoke for obstetric surgery, which he thought was more particularly indebted to the Listerian methods. The terrible mortality at the maternity hospitals was now a thing of the past. He concluded by exclaiming: "Lord Lister, when we are asked why you are illustrious we reply because you have driven back Death itself; because in all you have done you have only caused tears of joy and gratitude."

After a few words of admiration on behalf of the Paris medical students by the President of the Students' Club Lord LISTER rose to reply. He spoke slowly, gently, and in French. When he received the invitation to that banquet, he said, he was overwhelmed by the honour; but he accepted it because he interpreted the invitation as an expression of the respect of French scientists for the noble science of surgery and for the Royal Society of which he was President. He also thought that such a fête given by such eminent Frenchmen to an English scientist was a striking illustration of the happy fact that though there were animosities—or, rather, he would prefer to say misunderstandings—science knew nothing of them. Scientists had learned to respect each other—better still, to love each other—whatever might be their nationality. He had often stated, and he was pleased to repeat it, how much he was indebted to Pasteur. He had ever loved physiology and surgery, but he had lamented the disastrous results that followed even the best and most skilful operations. He saw that the chief evil was due to changes that occurred after the operation and to a cause arising not from within but from without the patient's body. He did what he could to guard against this, but all efforts were useless till Pasteur threw a powerful light on the subject. Pasteur had suggested a possible course which he, the speaker, had done his best to follow. That was all. If the results had been so beneficent as generously described by the various speakers that night it had been in a great measure due to accident. Lord Lister then renewed his expression of gratitude for the reception he had enjoyed and said that the memory of such a demonstration would never be effaced from his mind.

It would be difficult, nay, impossible, to fully describe the effect produced by Lord Lister's speech. The simple, brief sentence, "That was all," was more particularly commented upon. The extraordinary modesty and simplicity of bearing of the great British man of science evoked endless expressions of surprise. How was it possible to receive so many honours and yet not to be in the least degree spoilt by them? That seemed to be considered as wonderful and as exceptional as the services and the discoveries which all present sought to honour in the person of Lord Lister.

Lord Lister was then conducted to the Medical Club in the Avenue de l'Opéra, where he received a great ovation. The president of the club, Dr. Pozzi, wished Lord Lister in eloquent terms the heartiest welcome and suggested that a marble tablet should be put up in the club in commemoration of Lord Lister's visit. The greatest enthusiasm prevailed throughout.

THE OPENING CEREMONY.

(FROM OUR SPECIAL COMMISSIONER.)

By half-past one in the afternoon of Thursday, August 2nd, a long line of cabs was hurrying over the Pont de la Concorde, manœuvring round the Place des Invalides and seeking short cuts to the rear of the Gallery of Machines where is situated the nearest entrance to the Hall of Festivals. The man in the street was somewhat amazed by the presence of so many persons in full dress at this early hour, together with the display of many orders and decorations and brilliant uniforms, and all apparently going in the same direction. The weather, rendered cool by recent rains, was delightful and the members of the Congress for the most part rode in open carriages, to the great satisfaction of the Parisian crowds who were thus better able to contemplate the distinguished visitors and guests of their great town. The garde municipal à cheval guarded the approaches of the great hall, and, within, the republican guards, with their best plumes and newest uniforms, kept the passage clear for the members of the Congress. Though on that very day the computation had been made that the Congress numbered 5739 members—and there were wives, relations, friends, and journalists present not included in this number—still the great Hall of Festivals was not half full. It may be remembered that last year I described a conversation I had with Dr. Chauffard. The secretary-general of the Congress then lamented that there was no suitable hall in Paris for the opening ceremony. There had been some 5000 members when the Congress met at Moscow and there might be twice as many when it met in Paris. We did not then anticipate that a war would considerably reduce the British contingent or make sufficient allowance for the competition of other congresses and the fear of the cost of living in Paris during the Congress—a fear, by the way, which events have not justified, at least for those who knew their way about. Dr. Chauffard and myself did not then realise that a great Hall of Festivals would be built. I suggested the Trocadéro, but Dr. Chauffard is an artist and he could not bear the idea of bringing together delegates from all the world in a hall which could only boast of its size and which altogether failed to illustrate the artistic taste and capacities of the French people. Dr. Chauffard must now be well satisfied. No one can fail to have been impressed by the artistic beauty and grandeur of the Hall of Festivals. The domed stained-glass roof shed a rich yellow light on the great circle below which was about half covered with velvet benches. Between the four entrances on the four sides of the circle were vast tribunes or rising galleries where some hundreds of people could be seated. One of these served as the platform and was luxuriously furnished with gilt and red silk chairs, on another of these tribunes there was a military band, and the remaining two were occupied mainly by ladies. The benches in the body of the hall were divided by broad avenues, and each division was allotted to members under various classifications. On the platform academic and military uniforms helped to enliven the scene. The President of the Congress, Dr. Lannelongue, was resplendent in the bright green embroidery of the uniform of the members of the Institute, and Professor Marey was also in the same cheerful dress. Those who belonged to the Academy of Medicine but not to the Institute had their coats embroidered with more sober colours, violet and gold. Among the distinguished crowd occupying the platform I noticed M. Faillières, President of the Senate,

talking to his fellow Senator, the celebrated surgeon Dr. Labbé. Professor Bouchard, who presided over the French Section at the Berlin Medical Congress, was not far from Dr. Dujardin-Beaumetz, the chief of the sanitary services of the army, who ranks as a general of division, and Dr. Cuneo, chief of the sanitary services of the navy. At one time there must have been not far from 150 persons on this vast tribune.

At a quarter past two the republican guards advanced into the body of the hall and cleared the central passage and made an open space at the foot of the tribune. Five minutes later the band played the "Marseillaise." Everyone rose and strained to get a glimpse of the President of the Republic; but in spite of the national hymn which generally heralds his presence the President was not there. While the audience were still looking and wondering Dr. Lannelongue had taken the chair and half sentences or stray words were heard—"an appalling crime"—"sympathy"—"prevents the President of the Republic attending any public"—"sympathy of the whole assembly"—"horror at such an attempt"; and though but few heard a complete sentence everyone understood perfectly what was meant. Then the assembly sat down; and, after having explained why M. Loubet was absent, Professor LANNELONGUE proceeded to read the opening discourse; but soon there arose a strange sort of sound, like the beating of pebbles by the waves on the seashore. It was the effect of whispered conversation complicated by the incalculable echoes of the great hall. Professor Lannelongue read in a loud and distinct voice and slowly, but it was like speaking to the ocean. He said that the object unceasingly pursued was the improvement of mankind, and for this absolute freedom of research was necessary. Such researches would be materially facilitated if a nomenclature more in harmony with present knowledge could be universally accepted. After pointing out that the idea of an International Medical Congress was first brought forward at Bordeaux in 1855 Professor Lannelongue paid a handsome tribute to the help and support given by medical men of all nations and cordially welcomed all the members of the Congress.

M. MONIS, the Minister of Justice, followed and in the name of the French Republic greeted the leaders of civilisation. The French Government was anxious to show its respect for a profession representing devotion to humanity and for men who had come from all parts of the world to promote the cause of science based on truth.

The General Secretary, Dr. CHAUFFARD, followed, and then came the long procession of foreign representatives, headed by Dr. VON BERGMANN of Berlin, who spoke in a loud voice and was greeted with great applause. Though portly in figure his coat was almost entirely concealed by the numerous orders, stars, and decorations that have been conferred on the renowned German surgeon. Then appeared four other members; their names were not announced, though one of them was stated to be Dr. CASTILLANI of the Argentine Republic. They spoke in dumb show and fortunately very briefly. Dr. HINGSTON of Canada, who came next, was heard a little better and met with a hearty ovation. I caught some words about science that recognised no frontiers, and about duty. When he sat down, after uttering but a few words, a delegate from Chili spoke, and then Dr. CARTEJARENA on behalf of Spain. America, Greece, Japan, and other nations had their speakers, but the only real orator was the representative of Mexico. He knew how to step forward across the broad platform and was the only speaker who had the courage to go right forward to the place specially devised for the speakers to stand. He knew also how to manage his voice, and though at that moment no special interest was felt with regard to Mexico everyone was delighted to see a speaker whom they could hear. It is true that he indulged freely in platitudes, but then they were so well delivered that it was a great relief after the weariness of the previous inaudible speakers. He extolled Pasteur and the happy country that had given birth to a man who had won the title of a citizen of the world. When a brave man died all died with him; but when a man of genius died he did not disappear. Such men only died like the sun to reappear very soon, for their works continued to illumine the world. After more speeches suddenly the band began to play a lively tune, and it was inferred that by this time every nation had had its say.

But the ceremony was not over. The best was to come. Professor VIRCHOW of Berlin had to deliver an address on Traumatism and Infection, alluding to the influence of the French schools on science. He set to work in true German style thoroughly and completely to develop his thesis. He spoke in German, and very few persons present could have understood him even if they had been able to hear him. This finally broke the patience of the audience, which soon melted away, and three parts of the persons present had disappeared by the time the learned professor had finished. The gist of his remarks was as follows. Traumatisms might be defined as an alteration of any portion of the *living* body brought about by external violence. Traumatisms might be divided into visible, such as wounds, and hidden, such as contusions. A wound being necessarily accompanied by a solution of continuity it was very prone to collect foreign matter, either in bulk or finely divided, as in the case of dust. This was the way in which harmful matters brought about infection. Contusions, on the other hand, were capable of infection only by internal substances. There were cases, however, where a contusion without any superficial lesion was produced by external violence and in which, despite the integrity of the surface, infection supervened. Such, for instance, were the dangerous inflammations of the marrow of the long bones, although in such cases the skin, the subcutaneous tissue, the muscles, and the periosteum showed no alteration. Innumerable microbes were found in the affected parts of the marrow. Whence did they come? That was a question which could very rarely be settled by observation but which opened the door to hypothesis. General opinion at the present day favoured the theory of bacterial origin, according to which an infection already existing in the blood must be presupposed, produced at the seat of another wound, and carried to the focus of the secondary manifestation. Some surgeons considered that there must be some very minute erosion of the surface at the seat of contusion. Both these explanations were theoretical and had no definite proof. It was extremely difficult to prove that the traumatism and the infection were synchronous. Observations were on record where the infection preceded the traumatism and others in which it developed in a part wounded a long time previously. In cases of this kind a decision could only be arrived at by a careful consideration of the history of the case. If this was not to be obtained the anatomical points of the affection must be looked into. The great *savant* was proceeding to illustrate this point by special examples when a large part of the audience dispersed. There is not a centre of scientific thought in the world where Professor Virchow's inimitable achievements are in higher repute than in Paris. The apparent discourtesy was due to the fact that he was almost inaudible and speaking in a language with which many were not familiar.

It was then announced that Professor PAVLOV from Russia, who was to have delivered a discourse, had been detained through illness. The faithful few who had remained in the great hall then quickly dispersed. It must be confessed that this opening ceremony was dull.

In the evening Dr. Lannelongue received more than a thousand members of the Congress. It was a brilliant entertainment. There was some good music and then the children's ballet corps of the Grand Opéra danced and appeared bearing flags of the different nationalities. The band accompanied this display with the national hymns of Russia, England, Germany, Austria, and France.

THE GENERAL ASSEMBLY AT THE SORBONNE.

On Monday afternoon a general assembly of the whole Congress was held in the new hall of the Sorbonne. This magnificent building can seat 3000 persons and there were probably close upon 2000 present. The President of the Congress, Dr. LANNELONGUE, opened the proceedings at 12.15 P.M., and the General Secretary, Dr. CHAUFFARD, read out a long list of honorary presidents of sections whose nominations the assembly at once and readily notified. Professor LIKHATCHEFF then read on behalf of Professor Pavlov, who was absent through illness, the paper which he should have communicated at the opening ceremony. It dealt with Experimental Therapy as a new and fruitful method of physiological research. This lengthy and technical paper described many experiments made with dogs and concluded by a special homage to Claude Bernard.

Dr. LANNELONGUE then explained that Professor Baccelli was to have read the next paper, but in consequence of the national mourning refrained from doing so. He expressed,

on behalf of the Congress, sympathy for their Italian colleagues and called on Professor Burdon Sanderson. Speaking in French Sir J. BURDON SANDERSON explained that 47 years ago he had come to Paris to terminate his medical education and felt especially honoured, at the close of his career, at being thus able to speak in France to such a distinguished audience. These introductory remarks were delivered with some timidity and hesitation and only a few persons seized their meaning and faintly applauded; but when he entered into the subject matter of his paper—Some Modern Pathological Problems—his voice rose, his pronunciation improved, and the force of his diction as well as the subject matter of his remarks elicited several outbursts of applause. Professor JACOBI from the United States followed and gave a very interesting account of the growth of the medical profession in America, of its medical education from its crudest beginning to the present day, and of the American medical press. This was all quite new to the greater part of the audience and was consequently welcome and entertaining. These three papers were lengthy and sufficed to fill up the afternoon. Indeed, a good many persons left before it was over, though others came in to take their place. I do not know whether many persons noticed the admirable ventilation of the hall which in this respect is one of the model halls in Europe. The fresh pure air was filtering in all the time from every seat and was so carefully propelled forward that its passage could only be just faintly perceived by those who specially sought to note its passing. The readers of THE LANCET may remember the full description and illustrations of the system employed which were published in your columns some 10 years ago when the new hall had only been in existence a few months.

THE FÊTE AT THE LUXEMBOURG PALACE

As already announced all the official entertainments have been postponed, and it was at first generally supposed that the fête to be given at the Palace of the Luxembourg announced for August 6th would likewise be abandoned. This ancient palace being now the meeting-place of the Senate it was naturally supposed that the Upper House was desirous of receiving the members of the Congress, and this could not have been otherwise than an official reception. It appears, however, that these conjectures were mistaken. It was the members of the Bureau, or managing committee, and the committees of the sections who had organised the fête, and they had simply borrowed the *locale* of the Senate for that purpose. Therefore, though the Congress is indebted to the Senate for a certain measure of hospitality—namely, the use of the Senate House—nevertheless it was not the Senate that was giving the *fête*, and therefore it fell under the denomination of a private and not an official entertainment. Consequently it was not postponed, and as it was the only large festivity occurring during the week everyone made a point of going there, and the number of members has considerably increased since the opening day. On August 5th it amounted to 6170, and including the wives and families of the members, together with various officials and notable personages who are not members of the Congress, the number of those who were invited must have amounted to some 10,000. The programme was most attractive. In the gardens there was to be a military band, in the ballroom there was to be dancing to an orchestra of 45 musicians, and in the Salle des Fêtes another orchestra of 45 musicians were to accompany Madame Litvinne and M. Renaud from the Grand Opéra who, with others, sang selections. This was to be followed by an operetta, some dancing, and recitations by M. Mounet-Sully, of the Comédie Française, and Madame Sarah Bernhardt. Obviously there were here all the elements necessary for a most refined and enjoyable *soirée*. Unfortunately the results were entirely marred, firstly, because by far too many invitations were issued; and secondly, because there were no stewards within the building to guide the guests and to prevent crushing.

In the streets, round the Palace, there were a great number of police who with their white staffs regulated the traffic and got the carriages in and out of the great yard with perfect order and promptitude. But after this all semblance of organisation ceased. The cloak-rooms provided were altogether too small and the attendants were overwhelmed. Many guests had to wait half an hour, some a longer time, before they could get numbers for their cloaks, and this in a terrible crush of people. Then when they attempted to enter the Palace they found that there was only one door and that it was only four feet wide. At first, however, this only meant some delay and some squeezing. But the early arrivals soon found that the building was getting intolerably hot and overcrowded. The seats to hear the music were all filled at a very early hour. To stand closely packed in the aisles between the seats or in the passages outside where nothing could be seen or heard became both dull and wearisome, and before 11 in the evening a strong outward current set in. But by that time the banquet given by the surgical section at the Hôtel of the Palais d'Orsay, which is not far off, had terminated, as also a number of private dinners, and a large crowd of late arrivals coming from these minor entertainments now flocked to the Palais du Luxembourg. It was at this point that the want of stewards became manifest. Those who were already tired and wanted to go home knew of no exit save the door by which they had entered; and here and in the approaching passages they met the incoming crowd. Soon a terrific contest occurred between the out-goers and the in-comers which often resulted in a deadlock. Sometimes one side had the advantage, sometimes the other. For my part I was for a good quarter of an hour unable to move either backwards or forwards and had some difficulty in keeping my coat on my back. Several gentlemen had their collars torn off, their neckties disappeared, and fearful havoc was made of the ladies' dresses. I do not, however, believe that anything serious occurred, though some ladies must have suffered from the alarm which they very naturally experienced. There were, it appears, other doors intended to be used solely as exits, but not one person in 20, perhaps not one in 100, knew of their existence. The struggle at this one door probably lasted for a couple of hours; in any case, I was present for more than an hour while it continued. Reaching finally the open I witnessed a most remarkable sight. Here in the great yard, with its old-fashioned huge square paving-stones that in the olden days supplied the principal material for throwing up barricades, were gathered in clusters from 200 to 300 ladies and gentlemen. A few chairs had been discovered and some were quietly sitting down enjoying the cool of the evening. Ladies in low-neck dresses, officers in embroidered uniforms, and all the gentlemen in evening dress, contented themselves with loitering in the yard intended exclusively for carriages, and watching the struggle at the one door and hearing the stories of those who come out of the broiling crush from within. A great many guests, after waiting a considerable time, went home and never succeeded in entering the Palace at all. Among those who were thus patiently and modestly waiting outside in the yard I noticed the Dean of the Faculty and Madame Brouardel. This morning Professor Brouardel told me that he finally discovered a small back entrance by which he managed to gain admittance. In his opinion also the chief blunder was the want of stewards to show people where to go and what to do. In the dancing saloon though the band piped there was no dancing worth mentioning in consequence of the crush. On the other hand, some German members specially distinguished themselves by conducting the most effective raids upon the buffets, carrying away the provisions, which they put upon chairs, and, grouping round these extemporised tables, managed to make hearty meals on sweets and sandwiches. As it is the custom in France to dine at seven or eight o'clock it is not generally thought necessary to provide substantial fare so soon after dinner. Commenting on the evening and its mishaps the *Fronde* of this morning says: "Our regret for the manner in which our guests were treated is somewhat lessened by the utter want of consideration some of them displayed towards us. Some foreigners thought fit to come to this entertainment in travelling jackets and we perceived some women wearing boating caps."

THE SECTIONS.

Early on Friday, August 3rd, the different sections opened their sessions, and although under paragraph marked B of what is termed "Analytical Programme of Business" it was specially pointed out that members had a right to take part in all the sections it is unlikely that many medical men did much more than attend one or two, perhaps only visiting some of the others. The sections, numbering 26, were scattered over a wide area and some trouble was experienced in finding the different buildings where the meetings took place. The École Pratique accommodated three sections in a large amphitheatre. Under the presidency of Professor

and to its transformation into actual gout, some of them being as follows: (1) all the circumstances being equal gout manifested itself earlier and with more severity when the uric acid diathesis was well marked than when it was not; (2) personal habits, such as idleness and luxurious living, or the combination of these two in a high degree, or the abuse of alcohol, favoured the development of gout and temporary variations might very often be attributed to those conditions; (3) certain acute and chronic toxic influences in presence of the uric acid diathesis favoured the development of gout, among which some bacterial toxins were of great importance, and the relations of gout to rheumatism, syphilis, lead-poisoning, and influenza must be kept in mind; and (4) neither contagion nor climate had any influence as regards gout. Uric acid seemed to be the poison which produced gout. The question whether other products of the organism, such as the alloxur bases or nuclein bases, also played a part was not yet decided. It was probable that it was only the uric acid formed at the expense of the nuclein substances of the human body, and not that formed at the expense of the nucleins of the food, which had an influence on the pathogenesis of gout. It was not yet proved that in gout uric acid was formed in excess; Dr. Ebstein considered that an increased formation of it was not indispensable, but was nevertheless very probable. The history of leukæmia showed that gout was not the result of over-production of uric acid (estimated according to the quantity of uric acid excreted in the urine), for in some cases of leukæmia there was an excretion of uric acid greater than ever occurred in gout. Uric acid was a chemical poison but not a septic one. Its effect was not the same either on animals of different species or on animals of the same species but of different ages. Inflammatory and necrotic changes of the tissues in question were the necessary consequence of the presence of uric acid which ultimately caused total necrosis. When the tissues were quite dead, but not before, the acid deposited itself there under the form of crystalline acid urate of sodium, called mono-natrium urate by Tollens and sodium biurate by Roberts. Tollens thought that uric acid circulated in the blood and in the alkaline fluids of the human body in this same alkaline combination, and not, as Roberts supposed, in the form of sodium quadriurate, a salt which Tollens has more correctly called hemi-sodium-urate. It might be admitted without hesitation that the mono-natrium urate of Tollens (sodium biurate of Roberts) could deposit itself in the crystalline form in tissues the vitality of which had been destroyed either by uric acid or by some other poison. In order to understand the pathogenesis of the different symptoms of gout it was necessary to presume the existence of primary articular gout and primary renal gout. The former was the commonest variety of gout and did not prevent the patients from attaining an advanced age. Primary articular gout developed itself at first under the influence of retained uric acid, this retention being localised because it affected only a single part or some parts of the human body. In primary renal gout there was from the outset a generalised retention of uric acid which affected all parts of the body and was always caused by primary structural disease of the kidneys.

Sir DYCE DUCKWORTH (London) followed with a paper on the same subject. Sir Dyce Duckworth's conclusions were as follows. 1. Gout as a morbid condition depended on an inherent vice of nutrition which was manifested by an imperfect metabolism in various organs or parts of the body, presumably in the kidneys and probably in the liver. 2. This trophic disorder or inadequacy (*ralentissement de nutrition*) led to the formation of uric acid, probably in excess, and to the periodic retention of it in the blood (gouty urichæmia). 3. Histology threw no light upon the intimate nature of this defect which thus related to cellular potentiality, possibly under neuro-trophic influence, and not, so far as was known, to structural alteration. 4. This textural disability or a tendency to it might be primarily acquired and also transmitted as a fault, thereby inducing from time to time urichæmia with gouty manifestations in the descendants. 5. In most instances under conditions which provoked it, and in some cases independently of these, attacks of gout might grow up and come to a crisis. Such crises were attended by an alteration in the solubility of the uric salt in the blood whereby irritating crystals of biurate of sodium were produced and precipitated in various parts of the body. 6. A paroxysm of gout, the sites of its occurrence, and its metastases were determined by nervous influences, probably dominated from the bulbar centre, and the local attacks alighted either in the joints or in textures which had been weakened or rendered vulnerable by impaired nutrition owing to past injury or over-use. 7. This central neurosis was an essential and transmissible feature in the pathogeny of gout and pertained to the arthritic diathesis generally. 8. The urichæmia of gout was peculiar and unlike that which was induced by other morbid conditions, but the occurrence of urichæmia in the gouty was by itself inadequate to induce attacks of gout. 9. Uratic deposits in any part of the body might be removed in course of time but were apt to be permanent in the least vascular tissues. 10. Uratic deposits might occur to an enormous extent in gouty persons without the occurrence of any pain or paroxysms. 11. The clinical features of gout indicated that both *hæmic* changes (due to inherent morbid tissue metabolism) and a *neuro-trophic disturbance* acted as pathogenic factors, and consequently gout was to be regarded as a neuro-humoral malady.

Diagnosis of Renal Insufficiency.

Dr. CH. ACHARD and Dr. S. LAACHE read papers upon this subject. Dr. Achard dealt chiefly (1) with the results of cryoscopy applied to the urine and blood serum, an index of the permeability of the kidney being thereby obtained, and (2) with the conclusions to be drawn from the elimination of a foreign body (usually methylene blue) in the urine.

Dr. LAACHE said that treatment ought to be prophylactic by preference, but if that was impossible the well-known methods of treatment in kidney disease ought to be followed. Special attention must be given to the state of the heart.

Muco-membranous Colitis.

Dr. ALBERT MATHIEU (of the Hôpital Andral, Paris), Dr. F. BOAS (Berlin), and Dr. JULIUS MANNABERG (Vienna) read papers upon this subject. Dr. MATHIEU said that constipation, often spasmodic, was the rule in muco-membranous colitis. Diarrhœa, which was always of short duration, was the result of an attack of catarrhal colitis. There was always in muco-membranous colitis a secretional irritation of the mucous membrane. The disease only showed itself in its full intensity in persons predisposed by previous neuropathic tendency. Nervous derangement produced hyperæsthesia of the walls of the large intestine and interfered with its motility. In treatment, castor oil, copious enemata, and belladonna were useful. Drastic purgatives, astringent injections, and massage should be avoided.

Dr. BOAS said that the only positive diagnostic symptom was the existence of the characteristic mucous masses; other symptoms, such as tenderness of the colon, coloptosis, moveable kidney, and intestinal atony, went no further than supporting the diagnosis. It was absolutely necessary to decide whether the muco-membranous colitis was idiopathic or a complication. Differential diagnosis was required only as between muco-membranous colitis and colitis mucosa. By frequent observations and the systematic employment of intestinal injections a decision would be almost always possible. The clinical history of muco-membranous colitis was exactly parallel to that of habitual constipation, and methods of treatment which were suitable for the one were also suitable for the other.

Dr. MANNABERG said that a distinction must be drawn between enteritis membranacea and colitis mucosa. By the former name was understood a sub-acute or chronic catarrhal affection of the large intestine accompanied by evacuations particularly rich in mucus. Colitis mucosa was the name of a morbid condition characterised by paroxysmal attacks of colitis followed by the evacuation of masses of mucus. The former variety was, in fact, only a catarrh of the large intestine, accompanied by an abundant evacuation of mucus; it had in a general way the same pathogenesis as catarrh of the large intestine. Colitis mucosa had, on the contrary, a special pathogenesis. In the great majority of cases its basis was a general neuropathy (hysteria or neurasthenia) and there was a tendency to consider it as a neurosis. The paroxysms might be induced by certain factors of occasional occurrence, the principal of which were diseases of the genital organs (both in the male and the female), mental disorders, constipation, irritating rectal injections, and organic diseases of the intestine. The pathological anatomy of enteritis membranacea was the same as that of enteritis in general. With regard to colitis mucosa, in the very rare cases in which an

milk was never woman's milk; it was not a curative agent; it afforded, however, the great advantage of destroying fermenting and pathogenic germs; that was why it was indispensable in large cities and during the prevalence of certain epidemics, and wherever fresh and unpolluted milk was not accessible. When employed as exclusive infant food cow's milk watered or not was liable to cause constipation, or diarrhœa, rickets, and scurvy. To preserve its bactericidal effect heat should be followed by immediate and rapid cooling, but not freezing. Ample dilution of the artificial food of the infant, and particularly of the newly-born, was required because of the heterogeneous composition of cow's milk; even those who were as usual put to an incompetent breast required water to combat loss of weight and the tendency to nephritis and to nephrolithiasis, the former of which was still more frequent than the latter, indeed very frequent. A large amount of liquid did not interfere with the motility of the stomach and did not cause dilatation, firstly because the normal infant was no glutton and secondly because absorption began at once. Easy and equal digestibility of the casein in woman's and in cow's milk was either asserted or denied by good observers. When cereal decoctions were mixed with cow's milk its casein was claimed and proven to precipitate in fine tufts. On the other hand, cereals were said to have no such effect any more than water. The digestibility of a certain amount of amylum, such as was contained in cereals, had been erroneously and persistently denied when it had long been proven both by experience and by experiments to exist. Cereal decoctions were the proper diluents for the surplus casein of cow's milk. Milk sugar was partly absorbed in the stomach, partly in the intestine, and partly changed into lactic acid. It was required for digestion and was an antiseptic. Not enough of it, however, could be given to have the latter effect to the same degree that was exerted by flours. Besides, milk peptones disappeared with acid fermentation. That was why milk sugar should not be given in large quantities but other carbohydrates in its stead. Cane sugar should take its place particularly as for the purposes of digestion there was milk sugar enough in cow's milk that formed part of every artificial food, and because there was a ferment in the intestine of the young which inverted cane sugar and rendered it absorbable. Besides, every other carbohydrate had the same power to protect albumin against putrefaction. Fat was added to cow's milk for the alleged purpose of increasing its nutritive property by preventing the loss of the fat and albumin of the tissues and by loosening and separating the minute particles of casein. It should be remembered, however, that even human milk often contained so much fat as to cause "fat diarrhœa," that the normal infant in the fæces eliminated unchanged fat in goodly quantity, that moreover the fat globules of cow's milk were larger, less numerous, and less absorbable than those of woman's milk, that the two fats were not equal chemically, and that the urine was liable after feeding with cow's milk fat to contain ammonium, and the gut toxins. The mineral constituents of cow's and human milk were different. The addition of chloride of sodium to artificial foods was required both for physiological and chemical reasons. Home-made artificial foods were preferable to the proprietary foods of the market for many reasons. The separation of the component parts of cow's milk by mechanical means and the recomposition of the same was a procedure of doubtful value. The experience of the physician and of the well-directed public at large was equivalent at least to laboratory and library theories based on facts that were *sub judice*.

Dr. O. HEUBNER (Berlin) read a paper upon this subject. He said that a scientific set of rules could not be drawn up for the artificial feeding of children except by a study of the healthy infant born at full time. As rules for feeding a healthy workman could not be laid down by the study of a diet of an invalid, so a normal infant could not be fed by studying the difficulties or successes obtained in feeding unhealthy children. This, however, was what medical men very generally did, because they were so constantly brought into relation with invalid children. The common sense of nurses, however, had always understood that nothing could replace the milk of the mother so well as the milk of some animal. The milk of the various domestic animals, especially that of the cow and of the goat, did not differ more from the milk of a woman than the various sorts of meat differed the one from the other, such, for instance, as pork and beef, which the healthy child, like the adult, could eat alternately. The intestine of the healthy infant was capable of digesting the milk of the cow just as well as the milk of a woman. The labour of digestion, however, was greater in the former case than in the latter, for large proteid molecules required a greater digestive effort than the small hydro-carbon molecules, and cow's milk was very rich in the former, while the milk of a woman was rich in the latter. Other difficulties of artificial feeding arose from infection or decomposition to which the milk of an animal was always exposed before the child got it. As regards this danger, the sterilising of milk was one of the most important advances made during this century. There was no need to boil milk for half an hour, it was quite enough to boil it for five or ten minutes, and even if the milk was only heated for 25 minutes to 65° it appeared to be sufficiently sterilised without undergoing any disagreeable modification either in its taste or in its nutritive value. If a dyspeptic infant had to be artificially fed it was quite another affair, for the digestive power was considerably weakened. It was not so much the proteid matters of the milk which offered the greatest difficulty, but the fat. There were various ways of getting over this difficulty. The quantity of fat and of proteid substances could be lessened by diluting the milk with boiled water and adding sugar so as to bring it up to the proportions which existed in the milk of a woman—that was to say, 7 per cent.; instead of the sugar some other carbohydrate might be added, such as powdered biscuits. On another plan the milk might be peptonised. Another plan was to add skim milk or to replace the sugar of milk by another sugar—namely, maltose. These were the principal plans which had been adopted in the preparation of artificial milk.

Dr. MONTI (Vienna) read a paper upon the Scientific Principles involved in Preparing from the Milk of an Animal an Equivalent Diet to the Milk of a Woman. He pointed out that the acidity of cow's milk could be reduced to that of the milk of a woman by the addition of carbonate of potassium. Coagulation should be arranged so as to take place in the same manner in the milk of the cow as in the milk of a woman. To do this equal quantities of cow's milk and of butter-milk should be mixed together and a little carbonate of potassium added. The proportions of casein, of fat, and of sugar could all be arranged to be in the proper proportion by the use of a mixture of milk and butter-milk.

Dr. AXEL-JOHANNESSEN (Christiania) read a paper upon the Sterilisation of Milk and Mode of Use. He pointed out that to sterilise milk completely by boiling at the ordinary atmospheric pressure it would be necessary to cook it for several hours; but sterilisation could be carried quite far enough by other methods, of which the best and simplest was pasteurisation at 70° C. Great care should be taken to look after the milk-supply so that the supply of raw milk should be as free from germs as possible. The milk after pasteurisation should be cooled down to about 17° C. and used within 12 hours.

Dr. VARIOT, of the Hospital for Sick Children, Paris, read a paper upon the Sterilisation of Milk from a commercial point of view so as to be applicable to the needs of a great town. He described the plan adopted in Paris which was as follows. The milk was put in bottles holding a quarter or half a litre. It was raised to a temperature of 115° C. and the bottles were then sealed by corks covered with paraffin. Milk so treated would keep 15 days or more. At the Belleville Dispensary 150 litres of this milk were distributed per diem to poor children. The greater number of these children could take this milk without difficulty, beginning at the age of from two to three months. At an earlier age than this it must be diluted with a third or a fourth of boiled water and a little sugar added. Even wasting babies had improved by the use of this milk, and out of 800 cases there had never been an instance of Barlow's disease. Rickets was quite exceptional as well as marked constipation or anæmia.

Professor D'ESPINE (Geneva), Dr. MARFAN (Paris), Dr. CONCETTI (Rome), Dr. VIOLI (Constantinople), Dr. ESCHERICH (Gratz), Dr. SEITZ (Munich), Dr. SCHLOSSMANN (Dresden), and Dr. GRAANBOOM (Amsterdam), took part in an interesting discussion.

Gastro-Intestinal Infection in Children at an Early Age.

Dr. ESCHERICH (Gratz) read a highly technical paper upon the Part played by Microbes in Gastro-intestinal

Diseases. He pointed out that by the use of the Gruber-Widal reaction it was possible to differentiate the variety of the bacillus coli existing in one individual both from that existing in another individual and also from those which were introduced with the food. Gastro-intestinal affections due to the action of bacteria must be classified according to their etiology.

Professor A. BAGINSKY (Berlin) read a paper upon the Gastro-Intestinal Affections of Children from the point of view of pathological anatomy. These he divided into—I.—Functional troubles comprising acute dyspepsia not marked by any important anatomical changes. II.—1. Anatomical alterations: (*a*) lesions of a catarrhal nature, such as sub-acute dyspepsia, accompanied by cellular infiltration of the mucous membrane; (*b*) infantile cholera with destruction of the intestinal epithelium over a large surface; (*c*) chronic gastro-intestinal catarrh; and (*d*) intestinal atrophy. All these latter processes—namely, from *a* to *d*—were accompanied by vomiting, diarrhœa, and colic. Assimilation was impaired and the functions of the liver and of the pancreas were disturbed. 2. Anatomical lesions localised in the follicles. These might be divided into (*a*) simple follicular enteritis accompanied by a moderate degree of fever, a slight pain, and the secretion of blood; and (*b*) severe infectious follicular enteritis. In this there were destruction of the mucous membrane and the formation of abscesses. III.—Both functional troubles and the more severe morbid processes were due to infection or intoxication produced from within. Such were the direct action of the normal microbes of the intestine the virulence of which was exalted under particular circumstances. They could also be produced from without by the influence of toxins derived from the food or by microbes introduced with the food which became virulent in the intestine or finally some poison might be contained in the food. IV.—Those morbid processes which were most often developed during the heat of the summer were caused by the common saprophytes or their toxins, but these microbes were not specific. Septicæmia arising from the intestine was very rare. Cases had been reported where the infection had been localised in the kidney and where the infarct had gone on to suppuration or necrosis.

Professor FEDE (Naples) read a paper mainly dealing with the Symptoms and Treatment of Chronic Forms of Gastro-intestinal Infection. The clinical features noted were very various as they depended upon the intensity, the duration, the complications, and the atrophy which followed the disease. As to treatment, rules of hygiene and of diet came in the first rank. In very acute cases nothing should be given but water and, as a rule, artificial feeding by means of a feeding-bottle should be given up and a wet-nurse substituted. It was of great importance to clear out and to disinfect the intestine. This could be done by such drugs as castor-oil or calomel and by washing out the intestine with some disinfectant solution.

Dr. MARFAN (Paris) read a paper upon the Causes of Gastro-enteritis in Infants. He said that dyspeptic gastro-enteritis arose mainly from improper feeding, that infectious gastro-enteritis was principally caused by germs in the milk of the cow being conveyed into the digestive tract. Toxic gastro-enteritis resulted from the introduction of some chemical poison into the digestive tract. Poisoning by drugs was not uncommon, but the usual source of poisoning was milk, due to its containing toxins which had been produced by the action of germs before sterilisation. Other kinds of gastro-enteritis were consecutive to various maladies, such as, for instance, measles, influenza, or diphtheria. Infantile cholera or summer diarrhœa seemed to be due to a combination of circumstances—namely, some alterations in the digestive secretions set up by the hot weather which brought about a kind of self-poisoning, the increased growth of microbes in the milk of the cow under the influence of high temperature, and, finally, the formation of microbes of toxins before sterilisation.

Infantile Tuberculosis.

Professor D'ESPINE (Geneva) read a paper upon Prophylaxis in Infantile Tuberculosis. He said:—1. Infantile tuberculosis was a parasitic affection acquired by contagion in the child in the same way as in the adult. There were, however, exceptional cases in which the infection was congenital, being acquired by way of the placenta. 2. The source of the contagion in the immense majority of cases was from the sputum of tuberculous adults. 3. Another source of contagion was by way of the milk of cows, or very occasionally of goats, which were suffering from tuberculosis of the mammary gland. This mode of infection played a more important part in the infant than in the older child. 4. In infants up to the age of two years kissing by their mothers or nurses who were affected with phthisis appeared to be the usual mode of transmission. Sometimes contagion was carried directly by aspiration into the bronchi of saliva which contained bacilli. 5. In the child of between two and six years of age tuberculosis was very frequent and, as a rule, commenced in the bronchial glands. The greater frequency of tuberculosis between the ages of two and six years was explained by the habit which children had of putting everything in their mouths and of sucking their fingers. 6. From the age of six years up to that of puberty the frequency of tuberculosis commenced. There was a very real danger of contagion owing to the circumstances of school life, but in D'Espine's opinion this danger had been exaggerated. 7. The infection of tuberculosis occurring through the skin was very exceptional. 8. Hereditary predisposition played an important part in the production of tuberculosis in the child. It was therefore necessary that prophylactic measures should be specially applied to the children of tuberculous parents. Measures of prophylaxis might be divided into two classes—namely, those which went to diminish the danger of contagion and those which raised the resistance of the child to the infective organism. In the first class measures directed towards giving the child a supply of healthy milk might be included. Precautions must be taken that the nurse under whose care the child was placed should be free from tuberculosis. If the mother was phthisical the infant must be suckled by a healthy nurse. If the child came of a tuberculous family the general prophylactic measures recommended by the Academy of Medicine must be attended to. In schools no phthisical person should be allowed to be either a master or a mistress. Measures for raising the resistance of the children were as follows. The building of homes in the country to which poor and weakly children could be sent. Holiday camps should be provided for scholars and any predisposition to tuberculosis in its earliest manifestations should be fought against by sending children either to some mountain station or to the sea.

Dr. HUTINEL (Paris) read a paper on Heredity in Tuberculosis. He spoke as follows: Tuberculous heredity might show itself in three ways—by a transmission of the germ itself, by transmission of the predisposition, or in various nutritive trouble. 1. (*a*) Transmission of the germ at the time of conception was at present nothing more than a hypothesis; and (*b*) it was possible, however, that the fœtus could be infected before birth through the placenta. 2. Heteromorphic heredity. 3. Hereditary predisposition. 4. Prophylaxis. From the point of view of prophylaxis the part played by the medical attendant was very important. He should pay special attention to—1. The protection of tuberculous children against infection by bacilli. 2. In tuberculous children one great danger to be guarded against was the existence of latent centres of tuberculosis which were capable of giving rise to auto-infection. 3. In phthisical children all troubles incident to growth ought to be carefully attended to where there was any suspicion of a predisposition to tuberculosis.

Professor MOUSSOUS and Dr. RICHARDIÈRE (Paris) both read papers upon the Clinical Forms of Tuberculosis in Early Life. These papers tended to show that the tuberculosis of early life was usually of a generalised form, or perhaps it should be said that it started as a local disease of one organ and became generalised during the later period of its course. The favourite point of starting of the disease was the lymphatic glands. In cases of doubtful diagnosis Professor Moussous considered that the serum reaction which had been studied by Arloing and Courmont was of great value. Dr. Richardière, however, considered that at present this method could not be universally used.

Acute Non-Tuberculous Meningitis.

Dr. MYA (Florence) read the first paper upon this subject. By far the greater number of cases of meningitis of infancy, he said, were produced by the micro-organism of Weichselbaum, meningococcus intracellularis meningitidis. The clinical types of disease brought about by this micro-organism could be reduced to two—(1) the acute type characterised by stiffness of the neck, vomiting, rigidity of the muscles, and high fever. If a post-mortem examination

was made the whole surface of the brain would be found covered with a fibro-purulent exudation. The micro-organism was easily found and would bring about the typical symptoms of the disease in animals if injected into the sub-dural space. The disease generally lasted from three to 10 days. 2. The sub-acute type produced a disease which might last for some months, and the disease described by Carr as *simplex basis posterior meningitis* belonged to this category. The symptoms were much the same as in the acute disease, only generally very much less marked. The micro-organism was only very sparingly found, and if injected into animals did not produce the same symptoms. There was a form of meningitis which was only very rarely observed and which was due to the streptococcus pyogenes; but this form was almost always secondary to septicæmia developed within the cavity of the skull.

Dr. NETTER (Paris) read a paper upon the same subject. He said that a variety of cases of meningitis was due to other causes than tubercle; for instance, meningitis might arise as secondary to various diseases such as otitis, typhoid fever, or pneumonia, or it might be a primary disease such as was seen in epidemic meningitis. With regard to the diagnosis Dr. Netter said that it was impossible to put too high a value upon Kernig's sign. Cases where this sign had been met with where there was no meningitis were so rare that they were almost justified in asking whether the absence of meningitis was really definitely proved. As to treatment that by means of hot baths introduced by Anfrecht was of the greatest value.

III.—SURGERY.

GENERAL SURGERY.

Pancreatic Surgery.

Professor CECCHERELLI (Parma) arranged his conclusions under 24 headings, of which the following were the principal:—(*a*) Emaciation, presence of fat in the fæces, sugar in the urine, bronzed skin, jaundice, and pain were met with in the majority of pancreatic affections. (*b*) Complete extirpation of the pancreas was difficult on account of its deep situation and its intimate connexion with important viscera rich in vessels and nerves. (*c*) Surgical intervention was more justifiable at the small end of the pancreas than at the head. (*d*) Extirpation should not be attempted in cases of tuberculous or syphilitic lesions. In partial extirpation one of the two canals must be left. (*e*) Pancreatic tumours were generally either blood cysts following injuries or retention cysts. In the latter case surgical intervention was useful, but should be limited to excision of the cyst. It was necessary to keep in mind the question of opening Wirsung's canal and the probable discharge of pancreatic juice into the abdominal cavity. (*f*) Pancreatic calculi might be extracted. (*g*) Necrosed fragments of the pancreas might be removed. (*h*) In suppurative or gangrenous pancreatitis the rule was to do nothing during the acute stage. For the treatment of abscess or gangrene of the pancreas three routes were available—the lumbar extra-peritoneal, the transpleural, and the median supra-umbilical. (*i*) In hernia of the pancreas caused by injuries reduction and even fixation might be performed. (*j*) In contusions and wounds of the pancreas, if there were hæmorrhage it might be arrested either by sutures or by tying the bleeding vessels. Clots of blood in the abdominal cavity should at the same time be removed. (*k*) Experimental pathology justified the fixation of moveable pancreas. (*l*) If from any cause the duct between the pancreas and the duodenum became closed a new passage might be made for the pancreatic juice or a pancreatic fistula might be established. (*m*) Stitches through the pancreatic parenchyma did no harm, and were tolerated as in the kidneys, the liver, and the spleen. (*n*) In suturing the pancreatic duct the stitches should not pass into the interior of the duct, as concretions were liable to be formed on them. (*o*) Regeneration of the pancreas had been observed. (*p*) After complete extirpation of the pancreas great development of the glands of Galeati had been observed, and especially a karyokinetic increase in the epithelia, leading to the supposition that the missing gland might be thereby replaced. (*q*) The thermo-cautery or galvano-cautery ought not to be used in extirpation of the pancreas.

Mr. MAYO ROBSON (Leeds) commenced his report on the same subject by stating that he was convinced that pancreatic affections were much more common than was usually thought. He based his remarks on his personal experience, he having operated on 40 cases of pancreatic disease and having seen a considerably larger number of cases in which operation was either not consented to or not thought advisable. Under "anatomical considerations" he dwelt on the importance of posterior drainage where practicable in acute and in suppurative pancreatitis. For reaching the main pancreatic duct he had found it practicable to incise the second part of the duodenum and lay open the termination duct from the papilla.

Cancer.—In over 50 cases which he had seen he had found cancer usually to occur after 40 years of age and he believed that the cases occurring earlier in life were in many instances chronic interstitial pancreatitis, which might resemble cancer not only in the symptoms but in the naked-eye appearance after death. After describing the symptoms he remarked on the importance of distinguishing between cancer of the head and that of the body and tail of the pancreas; he then discussed the diagnosis and advised that especially in young subjects, but also at times in older patients, a hopeless prognosis should not hastily be given before surgical treatment had been tried, as if the case turned out to be chronic interstitial pancreatitis a cure might result from treatment. In describing the treatment he thought that excision of the pancreas for cancer could seldom be feasible or justifiable except in those cases where the disease was limited to the body or tail of the organ, and then only when it was caught in an early stage. Of the 15 cases on which he had operated for the relief of symptoms by cholecystotomy or cholecystenterostomy, nine recovered and lived for some time in greater comfort. The important fact, however, that some of the cases operated on and thought at the time to be cancer of the head of the pancreas, but which recovered and were now in perfect health, showing the tumours to have been chronic interstitial pancreatitis and not cancer, led Mr. Mayo Robson to advocate operation in all cases not too far advanced, especially in young or middle-aged patients, not because much good would be done if the case were truly cancer, but under the hope that the tumour might be inflammatory and not malignant.

Pancreatic cysts.—He had operated on five cases of pancreatic cyst for which as a routine treatment he advocated incision and drainage which he had performed in four cases with three recoveries. In one case the cyst was so easily enucleated that it was removed in that way and the patient made an uninterrupted recovery, but his experience, not only in his own case, but others seen under the care of his colleagues, would lead him to believe that incision could only rarely be justifiable. In none of his cases were any pathognonomic symptoms present and he thought that the diagnosis must usually be made from the physical signs.

Pancreatitis.—He drew a parallel between the inflammatory diseases of the liver, such as infective and suppurative cholangitis and chronic interstitial hepatitis and similar diseases of the pancreas and its duct. He believed he had seen functional ailments of the pancreas ending in recovery that would come under the heading of infective catarrh of the pancreatic ducts, and he adduced positive evidence of suppurative catarrh of the ducts as well as of chronic interstitial inflammation of the gland. He believed that as diagnosis became more perfected these diseases would be more frequently recognised and awarded their proper place in medicine. He assented to the pathological classification proposed by Fitz, of dividing acute pancreatitis into suppurative, hæmorrhagic, and gangrenous pancreatitis, but for clinical purposes he considered the subject under acute, subacute, and chronic pancreatitis. In discussing the etiology he laid stress on bacterial infection as being the essential and immediate cause, but enumerated a number of extrinsic causes, such as gastro-duodenal catarrh, injury, and pancreatic and biliary lithiasis. The mode of infection he believed was nearly always through the ducts. He discussed the symptoms, signs and diagnosis, and remarked that although pancreatitis was a disease without exact pathognomonic signs the diagnosis could usually be arrived at by a careful study of the history, mode of onset, and the combination of symptoms and signs. A case of acute infective pancreatitis coming under Mr. Mayo Robson's observation was related; also four cases of the suppurative form which were operated on after abscess had formed; of two, in which the pus was evacuated by an incision in the loin, recovery followed; and of two opened from the front both died. In both cases leakage of pus

PAGE NOT AVAILABLE

deplored the frequency of the cases in which these fractures remained ununited and long before the antiseptic era he recommended a species of cutting operation—namely, the application of his sharp hooks. Malgaigne's hooks, however, were much more dangerous than incising the skin and uniting the fragments with silver or aluminium bronze wire. Examination of recent fractures of the patella by means of the Roentgen rays disclosed three obstacles to bony union. 1. Inequality in the size of the two fragments. The upper fragment being much larger than the lower one they could only be brought into apposition by means of a suture. 2. Multiplicity of the fragments. In addition to the principal fragments there were small fragments or splinters which made their way between the principal surfaces and prevented coaptation. 3. Displacement of the fragments. One of the fragments underwent a movement of rotation, so that the fractured surface of the other fragment met it on its outer aspect and the two fractured surfaces could not be brought into contact. All these various displacements being rendered visible by the Roentgen rays it became evident that an operation was necessary to gain access to the seat of fracture, so that the conditions above enumerated might be dealt with and the fragments wired. In his clinic Professor von Bergmann had obtained perfect bony union in more than 25 cases of this kind. The operations proved that callus was of a bony and not of a fibrous nature; photographs taken with the Roentgen rays clearly showed not only this but also the firm bony union and the metallic sutures embedded in the callus. Fractures of the patella were generally treated by operation. The question of operation was different in other fractures, as, for instance, in those of the lower end of the radius, a subject which had been specially studied by Dr. E. Gallois, whose treatise, "Étude Radiographique et Expérimentale," had greatly added to their knowledge of the subject. The treatment of fractures of the patella was almost always the same, but the case was different with fractures of the lower end of the radius, the treatment of which varied according to the nature of the fracture and the displacement of the fragments. Professor von Bergmann showed in a series of photographs taken in the surgical clinic of Berlin University the most important varieties of these fractures. Fractures of the tarsal and metatarsal bones were almost unrecognised before the discovery of radioscopy. The symptoms of these fractures were attributed to an inflammatory swelling of the foot or to a contusion, and they were treated by massage which increased the displacement of the bones. When the fracture was recognised and its position ascertained it must not be disturbed, but must be immobilised completely. Professor von Bergmann showed photographs of these fractures also.

Treatment of Infected Wounds.

Dr. OSCAR BLOCH (Copenhagen) argued that from a practical point of view every wound without exception ought to be considered to be infected and that infection and its complications were due to the retention of secretions containing microbes. Antisepsis and drainage ought therefore to be the rule and in order to avoid reinfection the wound ought to be dressed rationally. Carbolic acid was, he said, the best antiseptic, and the best applications were sterilised gauze dressings containing aqueous solutions of carbolic acid, and cotton wool. He had little confidence in internal antiseptic treatment, in febrifuge treatment, or in serum treatment, including the use of anti-streptococcic serum.

Dr. FELIX LEJARS (Paris) said that every accidental wound ought to be treated as an infected wound, even though no indications of such infection might be present. The treatment ought to consist in careful cleansing at as early a period as possible, assisted if need be by excision, care being taken not to impair the vitality of the cells which form the natural defence of the living tissues and which have to be assisted in their protective actions. Sterilised water, artificial serum, and sterilised or boiled compresses fulfilled all requirements under this head. Antiseptic solutions were injurious when concentrated, and when diluted to such an extent that they did not interfere with the protective cells their action was in reality only a mechanical and cleansing one. Suppurating wounds should be exposed to the air, cleansed, drained, and dressed with some absorbent material. In cases of infected wounds, whether suppurating or not, specific serum treatment was indicated, but their resources in this respect were unfortunately very limited; anti-tetanic serum was only a prophylactic; anti-streptococcic serum had been employed chiefly in puerperal infection and erysipelas. In some foul and gangrenous wounds oxygenated water was useful. In certain cases artificial serum treatment aided the natural resisting power of the organism, increased the blood-pressure, and promoted diuresis.

Intestinal and Gastro-Intestinal Anastomoses.

Dr. ROUX (Lausanne) said that intestinal anastomosis by lateral apposition was the most practicable of these procedures. Anastomosis was preferred in cases of numerous adhesions, of inoperable tumours, and of certain inaccessible inflammatory conditions, such as tubercle and actinomycosis. It was a preliminary operation in cases of operable tumours occurring in very feeble patients and in cases of pyostercoral fistulæ it was often quite successful. Gastro-enterostomy, on account of being less dangerous, preceded pylorectomy if the state of the patient rendered it desirable. In non-malignant disease of the pylorus and stomach, for which an easy evacuation of the gastric contents was required, gastro-enterostomy was preferable to pylorectomy and pyloroplasty. It was much superior to gastroplication and gastropexy. An ordinary sewing needle was the best instrument for suturing because it was only in this way that primary union of the mucous membrane could be obtained. Murphy's button was the best contrivance of its kind; it was reserved for the cases where it was necessary to count the minutes. In all these operations there was a surprising proportion of deaths from pneumonia.

Dr. SOULIGOUX (Paris) said that in the treatment of cancer and stricture of the bowel intestinal anastomosis was the most usual principal operation or it might be a complementary operation. In cases of acute or even of chronic obstruction of the bowel the formation of an artificial anus was to be preferred. When there was retardation of the onward movement of the fæces without obstruction, if there was a moveable tumour which could be easily removed enterectomy ought to be performed, but this operation ought to conclude with an anastomosis either latero-lateral or termino-lateral. If the tumour was adherent anastomosis was the only available operation. For cicatricial stenosis of the pylorus, or of the first portion of the duodenum, or for hour-glass contraction of the stomach gastro-enterectomy was the best operation.

THE SURGICAL DISEASES OF INFANCY.

Congenital Dislocation of the Hip.

Professor HOFFA (Würzburg) read a paper upon Cutting Operations in Congenital Dislocation of the Hip. He pointed out that in cases of this deformity the operation without cutting was the one to be preferred. The cutting operation which was the best for children of from three years up to eight was that in which a new cavity was made for the head of the femur by the operation after the manner invented by Hoffa and Lorenz. This operation must be done neither too early nor too late. The best time for it was between the ages of three and eight years. That surgeon would succeed best who was able to carry out complete asepsis. The wound need not be stitched. The after-treatment was of the greatest importance as the muscles were thereby strengthened. Ankylosis did not occur except when the wound suppurated and when the operation was done at too advanced an age. Complete cure was more often obtained when the deformity was on the one side than when it was on both, and it might be said that by the Hoffa-Lorenz operation a cure was quite possible both in the anatomical and in the functional sense. There was no reason to fear any interference with the growth of the pelvis owing to the formation of the cavity in this operation. In cases of one-sided deformity in patients who had passed their eighth year osteotomy was the operation to be recommended.

Dr. ADOLPH LORENZ (Vienna) then read a paper upon the Bloodless Treatment of Congenital Diseases of the Hip-joint. This treatment, he said, was to be preferred to the operative, for the latter was not without its dangers (2 to 10 per cent. mortality according to different statistics). The ankyloses and contractures, which frequently followed, required a tedious after-treatment. The injury to, or the extirpation of, the Y-shaped cartilage of the acetabulum might result in subsequent deformity of the pelvis, on account of disturbances in development. Among the bloodless methods the treatment by means of portable apparatus could be said to be without limit; but, as a rule, without result, in spite of this fact. The gradual reduction of the head of the femur

PAGE NOT AVAILABLE

excised and the operation should be practised *à froid*—that was to say, when the general phenomena of infection had disappeared and when the local lesions had lost their activity. Too much hurry in operating exposed the patient to the risk of disturbing the favourable course of the disease, for the acute stage of appendicitis generally terminated by a localisation of the lesion and by its resolution when it was treated from the beginning by rest, careful diet, ice, and opium. Too hasty intervention was liable to give rise to another danger—that was to say, it was quite possible to operate upon the patient who had not got appendicitis but some of the diseases which simulated it. The only reason for intervention during the acute stage was to empty the abscess of its septic contents and to drain it very freely. In cases of very chronic appendicitis giving rise to frequent acute crises resection of the appendix was in most cases sufficient to effect a cure. In some cases, however, it would be found necessary not only to remove the appendix but to divide various bands, to free coils of intestine, or to resect portions of omentum which had become chronically inflamed.

URINARY SURGERY.

Conservative Operations in Renal Retention of Urine.

Dr. KÜSTER (Marbourg) opened the discussion on this subject. He said that renal retentions could be divided into two groups: (*a*) primary retention—i.e., cystic or sacculated kidney; and (*b*) secondary retention—i.e., suppurating kidney, of which he should say no more, as that condition almost invariably called for a radical operation. The term "sacculated hernia" was applied to all the instances of primary retention produced by any obstacle to the flow of urine, whatever be the contents of the sacs. As a general rule these obstacles were situated in the ureter and almost invariably in its upper third. Renal retention due to some obstacle in the renal pelvis should be treated by a conservative operation—i.e., the affected kidney should be preserved even if the other kidney was healthy. Conservative operations might be divided into four groups. (*a*) Fixation of a displaced kidney (nephropexy of Guyon). This simple operation must be combined with others, such as detachment of the ureter. (*b*) Formation of an anastomosis between (1) one part of the ureter and another, (2) the renal pelvis and the ureter, and (3) the renal pelvis and the bladder. All these operations should have for their end the avoidance of dead spaces, which were conducive to the formation of urinary calculi. Without this precaution the procedure was harmful. (*c*) Plastic operations with or without resection of the ureter. 1. Pyeloptychy (Israel). 2. Excision of valvular formations in the ureter and transverse suture (Fenger). 3. Resection of a kink in the ureter. Oblique resection was preferable to transverse, which might only lead to the formation of a fresh stenosis. 4. Uretero-pyelostomy (Trendelenburg and Küster). (*d*) Partial resection of the kidney. 1. Resection of the pelvis with suture (Albarran). 2. Wedge-shaped section of the renal substance in cases of hydronephrosis occurring in a horse-shoe kidney.

Dr. CHRISTIAN FENGER (Chicago) continued the discussion of the subject. Remittent or commencing retention (and all retention was, in its early stages, as a rule, remittent) was a condition in which they should always consider the possibility of saving kidney tissue by re-establishment of the free passage of the urine. The obstruction might be located in the calyces, in a branch of the ureter, in the bottom of the pelvis, or origin of the ureter, or in the ureter. Obstruction in the first two places caused a local or partial cysto-nephrosis and demanded for the relief of the condition bisection of the kidney from its convex surface and division of the partition walls. Stenosis at the exit of the ureter (valve-formation, oblique implantation from unilateral dilatation) required operations which varied in accordance with the absence or presence of stricture at the upper end of the ureter. If there was no stricture at the upper end of the ureter the valve-formation might be overcome by a trans-pelvic operation (Fenger, Mynter, Trendelenburg, Küster), or by extra-pelvic operation, which he preferred. If there was a stricture of the ureter at its exit from the pelvis, as might be expected in infected cases, they might resort to extra-pelvic plastic operation (Fenger), or to resection of the strictured end of the ureter, implantation of its upper divided end into the pelvis (Küster). If the stenosis or obstruction was located in the ureter it must be dealt with according to the laws laid down for surgery of the ureter—namely, resection and reimplantation, or Dr. Fenger's plastic operation. Were the results of these, so to speak, tentative conservative operations permanent, or did relapse eventually occur? In five of his cases no relapse occurred. The conditions were as follows:—1. Valve-formation; trans-pelvic operation; no relapse six years later. 2. Stricture at the upper end of the ureter; extra-pelvic operation; no relapse six years later. 3. Valve-formation of lower branch of the ureter; extra-pelvic operation; bisection of kidney, division of partition walls; no relapse after three years. 4. Excision of valve in the ureter by Dr. Fenger's plastic operation; no relapse after three years. 5. Stone in upper end of the ureter removed by Dr. Fenger. One year later a plastic operation on the ureter was performed by another surgeon. Six months later complete occlusion of the ureter at the site of the second operation was relieved by Dr. Fenger's plastic operation; no relapse after one year. In two cases relapse occurred under the following conditions:—1. Valve-formation without stricture, intra-pelvic operation, relapse of stenosis, occlusion of pelvic orifice; nephrectomy one year later. 2. Patient operated on by another surgeon, later by Dr. Fenger; operation was incomplete, failed, and nephrectomy was finally necessary.

M. BAZY (Paris) followed who said that renal retention was said to exist when the urine remained permanently in the renal pelvis or calices owing to some obstruction to its outflow. This obstacle might be situated in any part of the ureter, in the bladder, or in the urethra. To-day he should only consider the first named. Obstruction might be due to stricture, to a kink, or to a vicious insertion, or to a calculus. (The sites of these various obstructions were then considered.) Renal retention might be remittent, intermittent, or chronic, and, what was very important, septic or aseptic. Conservative operations were not indicated except when the kidney appeared capable of doing its work. But in a case where there was only one kidney a conservative operation was indicated whatever was the state of that kidney. Treatment would vary considerably according to the circumstance of the case. Calculi might be removed; kinks sometimes got well spontaneously or might be removed by nephropexy. Abnormal insertions were amenable to treatment by plastic operations. Strictures could be in exceptional cases dilated or got rid of by an anaplastic operation. Such operations might be performed by the transperitoneal route in aseptic cases or by the lumbar route in septic cases. Transplantations of the ureter into the bladder should be done by the abdominal route. Operations by the vaginal route should not be done. Infection of the ureter or renal pelvis was no contra-indication, but renal abscess contra-indicated any anaplastic operation.—Dr. LEGUEU (Paris), Dr. KUMMEL (Hamburg), Dr. D'ANTONA (Naples), Dr. NANU (Bucharest), and Dr. CASPER (Berlin) joined the three previous speakers in a debate.

The Value of Surgical Interference in Tuberculous Affections of the Bladder.

Dr. SAXTORPH (Copenhagen) made the first contribution at the Congress to this subject. He said that the question of surgical intervention in tuberculous disease of the bladder must be answered by a reference to the origin of the infection and its extent. Miliary tuberculosis of the bladder—if, indeed, it existed—was only a part of a general tuberculosis, was not amenable to surgical treatment, and would therefore not be considered here. Vesical tuberculosis almost always arose from an old pulmonary tuberculous focus—sometimes from a very old one. The vesical infection occurred in two ways: (1) the tubercle bacilli were carried by the blood-stream to the kidney, whence they were transmitted to the bladder and infected its mucous membrane (descending infection); and (2) the bacilli were carried in the blood-stream to the prostate, the vesiculæ seminales, the testicle, or the epididymis, whence they infected the vesical wall by contiguity (ascending infection). The bladder was apparently very resistant to the infection of tubercle and was hardly ever infected primarily by the blood-stream (hæmatogenic infection). Vesical tuberculosis, then, being always of a secondary nature there was no radical treatment except removal of the source of infection by nephrectomy and more or less total resection of the ureter or by destruction of the tuberculous foci in the genital organs. If this mode of treatment could not be carried out any attempt at radical treatment of vesical tuberculosis would be found to be as useless as attempting to divide water into pieces with a knife.

The infection centre having been removed vesical tuberculosis might either undergo spontaneous cure or might be treated surgically. Surgical treatment, whether in the male or in the female, should always be undertaken by the abdominal route. The bladder being opened the diseased mucous membrane might be removed by scissors, cautery, or curetting. The patient should be in Trendelenburg's position and the bladder sutured or drained according to circumstances. After-treatment, both general and local, was indispensable. All surgical treatment should be undertaken as soon as possible after the diagnosis had been made certain by the discovery of bacilli in the urine. If the infection centre could not be removed palliative treatment might be undertaken for the relief of pain. Thus the bladder might be opened by the abdominal route and the most diseased patches scraped. Drainage must be employed. It might be opened by the perineal route in the male and scraped and drained. In the female the bladder might be curetted through the urethra. The bladder might be washed out with a view to avoiding cystitis. The general health must be attended to.

Dr. HOGGE (Liège) followed with a paper upon the Surgical Treatment of Tuberculosis of the Urethra, Prostate, Testicles, and Vesiculæ Seminales. After discussing medicated topical applications he passed on to consider cutting operations for tubercle of the prostate. These operations, he said, had given good and lasting results in the hands of Guyon, Albarran, Zuckerkandel, and others. In tuberculosis of the testicle and epididymis total castration would appear to be from a study of the published results an operation only to be done exceptionally. The method of election was a conservative one consisting in resections. To sum up the matter, when the tuberculosis affected the prostate, the vas deferens, the vesiculæ seminales, the epididymis, or the testicle, an operation should be the rule when an abscess or fistula was present with or without fungation. The particular operation to be undertaken varied with the predilection of the surgeon, but some operation should certainly be done, as operation had a greater curative effect and was less risky for the patient than waiting and a purely medical treatment. Another element of doubt was the best stage of the disease at which to operate. Some surgeons counsel early operation in the initial phases of the disease, while others—and those the greater number—advised an expectant treatment. With regard to the extent of the operation, recent results of operations in which the disease was very widely removed would seem to show that for the future surgeons would be well advised to adopt free extirpation.

The Value of Surgical Intervention in Renal Tuberculosis.

Dr. POUSSON (Bordeaux) read a paper upon this subject. He said that surgical intervention for tuberculous disease of the kidney had hardly been in practice for more than 15 years, but operations multiplied so rapidly that from 1892 to 1895 he had been able to record an imposing series of statistics to which he had been able to add details of 161 cases collected in view of this paper.

I. *General results.*—(*a*) Immediate results. In 600 cases the mortality was 22·33 per cent. In the 161 cases which he had recently collected the mortality fell to 11·68 and in the practice of some surgeons it had further dropped to 8·95 per cent. (*b*) The operative mortality respectively of nephrotomy and nephrectomy was, taking all the cases together, nearly equal—namely, 20·8 per cent., as against 21·47 per cent. In the personal statistics of certain surgeons, however, incision of the kidney was more deadly than its extirpation in the proportion of 18·51 per cent. to 6·54 per cent. (*c*) The causes of death after either operation were suppression or deficiency of the urinary secretion. This occurred in 51 deaths out of 128. Other causes of death were shock, peritonitis, and injuries to other viscera or important vessels. Secondary results.—Of 63 cases operated upon by nephrotomy 39 died in the following year from progressive tuberculosis or other causes due to incomplete operation, and 24 were alive, of whom some were known to be living after the lapse of three, five, and even 10 years. All these patients, however, had lumbar fistulæ. Of 335 patients operated upon by nephrectomy 42 died within the year from diffuse tuberculosis and 295 others were living as follows: at the end of one year 33, from two to three years 41, at the end of five years four, at the end of six years seven, at the end of eight years two, and seven out of 105 had a fistula.

II. *Results in the different forms and clinical circumstances of the disease.*—Indications and contra-indications. (*a*) Of 10 patients operated upon for pain or hæmorrhage in the purely bacillary stage none died. The patients lived for a long time afterwards and preserved an actively working urinary apparatus. Intervention, then, having for its aim the removal of a quiet bacillary focus was undoubtedly legitimate. (*b*) In mixed infections the results were not so good. (*c*) Bilateral cases of lesion might be operated upon except when the other kidney showed very definite bacillary infection. A slight nephritis was no bar to either nephrotomy or nephrectomy. (*d*) As to the bladder the reflex pains of this organ often disappeared after operation. (*e*) The condition of the lungs and other organs and the age and sex of the patient have the same bearing upon these operations as upon any other.

III. *Results following upon different methods of operation.*—Choice of methods. (*a*) Nephrotomy should not be employed in the nodular or miliary form of tuberculosis. In the hydronephrotic form it should be always employed. So far it had been almost exclusively employed in the pyelonephrotic form, but, as a rule, only gave temporary results and even when most successful was followed by a fistula. (*b*) Primary nephrectomy was the operation of election; its mortality was only 21·79 per cent., whereas that of secondary nephrectomy was 30·76 per cent. The latter operation was, however, of considerable service. (*c*) With regard to the relative merits of the extra peritoneal and trans-peritoneal routes the former with a mortality of 21·2 was far preferable to the latter with a mortality of 34·04. (*d*) Partial nephrectomy should be altogether discarded.

The Remote Effects of Operative Treatment in Hypertrophy of the Prostate.

Professor A. VON FRISCH (Vienna) read a paper upon this subject. He said that of all the various operations for hypertrophy of the prostate only those which had for their object the complete removal of that portion of the prostate which prevented the free flow of urine offered any chance of lasting success. Such were subpubic and perineal prostatectomy, lateral prostatectomy, and Bottini's operation. The effects of all these were the more lasting in proportion as the passage was freed and remained free from cicatrisation. Operations done under the eye evidently answered best to these conditions, and such were the different prostatectomies. But they were always serious undertakings on account of the age and general feebleness of the patients in whom they were required. Bottini's operation was less dangerous, but not so free from risk as some would have them believe. Both classes of operation gave good and lasting results, even where the bladder was dilated and its muscular wall was apparently partly paralysed; a good result will follow if the obstruction be completely removed. However, no precise line of conduct could be laid down so as to assure success. The lasting effect of all these operations might be discounted by the formation of the new scar tissue or by a new hypertrophy of the gland.

Dr. F. LEGUEU (Paris) followed with a paper on the same subject. He said that there were three classes of operations for this condition: (1) operations on the testicles; (2) cystotomy; and (3) prostatectomy. 1. Of these, operations on the testicles sought to bring about atrophy of the prostate. In lieu of castration, which was considered by some to be too severe, division of the vas deferens or section of the vessels and nerves of the cord had been proposed. But all these were inferior in value to castration. As regards the remote results of double castration they were not so good as the early observations which did not take a long enough space of time into consideration would have had them believe. The prostate certainly shrunk but the patient improved to a far greater degree than could be accounted for by the diminution observed. The attacks of pain were less frequent and the contractility of the bladder improved so that the residual urine was less in quantity. But, after all, there was only amelioration and not permanent cure and comparing the results of castration with those of other methods it was doubtful whether the advantages of it were worth the sacrifice. 2. Cystotomy sought to make a meatus above the pubes. It doomed the patient, however, to incontinence of urine and the bladder could never empty itself completely. 3. Direct interference with the prostate appeared to be more and more the operation for the condition of hypertrophy. Bottini's operation could not yet be fairly judged from the point of remote results. Besides it was done in the dark and patients often relapsed owing to the new passage closing up again. Partial prostatectomy gave excellent

results in partial hypertrophy, but was of no use where the prostate was uniformly enlarged. Total prostatectomy could give very good results and apparently if undertaken by the perineal route at an early enough date before grave complications had set in seemed to be the operation of election for hypertrophy.

The Remote Effects of Structural Lesions in Urethral Stricture.

Mr. REGINALD HARRISON (London) read the first paper on this subject.[1] He summed up the conclusions to be drawn from his paper as follows. 1. That there was evidence to show that in peri-urethral strictures of the deep urethra the effects of divulsion as practised in Perrève's and Holt's operations might be limited to rupturing the dense stricture bands in the submucosa of the urethra, whilst the mucous membrane itself might escape any serious injury or laceration and was merely restored by stretching to its original dimensions. Here a permanent cure might result. On the other hand, where the mucous membrane was in itself the seat of stricture and formed part of the latter structurally, it was necessarily much torn or lacerated by the process of a sudden divulsion and the pathological condition consequently became assimilated with that of traumatisms of the urethra from external violence accidentally applied, which were followed by strictures of the most contractile and recurrent form. 2. That there was evidence to indicate that where the entire thickness of a stricture could be included within an incision of moderate dimensions made by an internal urethrotome the normal calibre of the urethra might be completely and permanently restored. Where this happened it might be concluded that all the fibres of contraction constituting the stricture were divided at the time of operation. And further that the converse was equally true. There was also evidence to show that the absence of recurrence under such circumstances was not necessarily dependent on the use of a bougie, though the latter was a precautionary measure which should invariably be advised. 3. That in the case of multiple strictures or strictures of the deep urethra of considerable dimensions either in their length or thickness treated by an internal incision of corresponding proportions, apart from other considerations, the tendency to reconstruction and recurrence with an additional amount of cicatricial material was frequent, the latter being probably due to the circumstances under which healing takes place in wounds of these dimensions so situated. 4. That lesions of the urethra demonstrated in various ways the poisonous effects that unprotected and confined urine was capable of exercising both on the body generally and on the tissues in constant contact with it, and that the liability to such effects was greatly diminished where drainage rendered these conditions of the urine impossible. 5. That in the case of recurring strictures previously treated by incision and in primary strictures of such length or extent as to require an internal section of a corresponding size, or as to which there might be doubt as to whether it would be safely possible so to include them, that for the purpose of the operation and its results such wounds should be made with due regard to other surgical principles than the one pertaining to the division of the contraction. 6. That there was direct evidence to show that the tendency to recontraction and recurrence of stricture after internal urethrotomy was largely diminished by the concurrent employment of systematic and thoroughly efficient urine-drainage, such as the combination of external urethrotomy, or perineal puncture, affords.

Dr. HERESCO (Bucharest) followed with a paper on the same subject. He said that they had to-day to consider the remote effects of internal urethrotomy, of external urethrotomy, and of resection of the urethra. Of these, internal urethrotomy was specially practised in cases of gonorrhœal stricture. Recent researches had shown that gonorrhœal stricture was really due to a sclerosis more or less complete and so simple section could not bring about a definite cure. Experiments upon animals agreed with clinical observations in man that if dilatation did not follow section of stricture cicatrisation was bound to follow. Dilatation was therefore the indispensable complement to internal urethrotomy. Internal urethrotomy, whether the incisions be superficial or deep, was bound to relapse. The date of this relapse varied according as dilatation was regularly kept up or not. He had known it occur five weeks after operation. In another patient it occurred at an interval of four months, in another at six months, and in others at one, two, and three years respectively. It had been known to occur after 30 years. External urethrotomy was practised in cases of so-called impermeable stricture, or where the stricture was complicated with fistulæ. Dilatation was indispensable, as in the case of internal urethrotomy. Relapse, however, was bound to occur, although Post, Van Buren, and Sayre have reported cases of cure lasting from 20 to 25 years after operation. Resection of the ureter was only feasible in cases of traumatic stricture. The essential condition for success was that there should be no suppuration. He would sum up his conclusions as follows. No cutting operation could bring about a lasting cure of stricture except resection of the urethra in certain conditions. Internal urethrotomy for gonorrheal stricture brought about no permanent result, it merely facilitated dilatation. Without dilatation the stricture would certainly relapse. The date of this relapse was uncertain, it might occur at any time from a few weeks to 12 years, and depended on the nature of the stricture and the regularity of the dilatation. External urethrotomy was open to the same objections as internal. But when the perineum was full of fistulæ and indurations external urethrotomy presented many advantages over the internal operation. Resection of the ureter under certain conditions brought about a permanent cure, but such conditions were rarely found. All cutting operations should be followed by persevering dilatation.

Dr. ALBARRAN (Paris) followed on the same subject. His paper may be shortly summed up as follows. In non-complicated inflammatory strictures the following methods were employed: electrolysis, dilatation, internal and external urethrotomy, resection, and autoplastic operations. Of these slow electrolysis gave better results than the rapid method, but there were not enough reported cases at present upon which to found a definite opinion as to remote results. Progressive dilatation gave good results, but had to be followed by the use of the dilating catheter. Internal urethrotomy could only be considered as the first step of dilatation. External urethrotomy was of use only in strictures of limited extent and must be followed by dilatation. Resection of the urethra in limited inflammatory strictures of the perineal region gave good results. If the stricture could be completely excised a permanent cure might be hoped for. Resection of the penile urethra might lead to curving of the penis. In inflammatory stricture complicated with fistulæ and tumours external urethrotomy should be performed. In traumatic stricture the operation of election was resection.

[1] The paper is published in full on p. 391.

IV.—OBSTETRICS AND GYNÆCOLOGY.

OBSTETRICS.

Etiology and Nature of Puerperal Septicæmia.

Dr. DOLÉRIS (Paris) read a paper on this subject. The genius of Pasteur, he said, had determined the microbic nature of puerperal septicæmia. They owed to him their notion of the existence, the virulence, and the contagiousness of puerperal pathogenic bacteria. The ordinary pathogenic germs found in puerperal septicæmia were the streptococcus, staphylococcus, gonococcus, and bacillus coli communis. Researches had shown that amongst the pathogenic organisms certain anaerobic forms, such as the bacillus putridus, must be included. A further conclusion was that some saprophytic anaerobic organisms could develop and act as true pathogenic germs, notably in cases of placental retention. The association of different species led more certainly to infection. The septicæmic condition caused death from toxic poisoning, which produced either nervous inhibition or intestinal paralysis. The staphylococcus might cause death by visceral metastases. The theory of autogenesis had recently received a new interpretation, according to which the pathogenic organisms existing in the pathological vaginal secretions should not be considered as saprophytic, and since autogenetic infection could not be distinguished from that due to saprophytic organisms this amounts to denying its existence.

Speaking on the same subject Drs. MENGE and KRÖNIG (Leipsic) understood puerperal fever as a malady of the puerperium in which pathogenic organisms infected the body as a whole. Fever might be entirely absent. They were unable to distinguish between the organisms which acted purely by their toxic properties and those which penetrated the tissues, nor could they distinguish with certainty between

a fever due to one or the other. The organisms causing puerperal fever were: streptococcus pyogenes puerperalis, staphylococcus, gonococcus, bacillus coli communis, bacillus diphtheriæ, diplococcus pneumoniæ, and certain imperfectly known organisms developing in the absence of oxygen, since they found them in puerperal lesions. The infection could be either autogenetic or heterogenetic. Gonorrhœal puerperal fever was to be regarded as due to the spread of an infectious process already existing in the body, not as an example of autogenesis. As the various organisms mentioned did not exist as saprophytes in the vaginal secretions of pregnant women an autogenetic infection by these organisms could not have as its seat of origin the vaginal secretion. Infection with anaerobic bacteria could not be denied since they were unable to distinguish with certainty between the anaerobic organisms causing puerperal fever and the anaerobic saprophytic organisms present in the vaginal secretion of pregnant women. Clinically they regarded as rare and of favourable prognosis an infection due to pathogenic organisms of saprophytic character derived from the skin of the external genitalia. The possibility of a puerperal infection being caused by organisms present as saprophytes in the cervical canal, the cavity of the uterus, or the tubes could be rejected since these cavities never contained such organisms. With regard to heterogenetic infection the number of germs present undoubtedly was a matter of importance. The difficulty in attempting to determine the varying degrees of virulence of different organisms was very great. They could only say that when an organism had lived a saprophytic existence for some time that its virulence was greatly diminished. Insufficient hæmostasis and marked lesions of the genital tract played an important part as predisposing factors. The primary seat of infection was most commonly the placental site or the endometrium; much less commonly the cervix, vagina, or perineum. The streptococcus had a great tendency to spread beyond the primary seat of infection either by the lymphatics or blood-vessels, while the staphylococcus often remained limited to the endometrium.

The Treatment of the Apparent Death of the Newly-born.

Dr. RIBEMONT-DESSAIGNES (Paris) read a paper on this subject. As a result, he said, of numerous causes which might occur during its birth the child might when born present the appearance of apparent death. Two varieties of asphyxia occurred, the blue and the white, while at times cases were met with in which both forms were present at the same time. Since in practice asphyxia was most commonly due to obstruction of the air passages by mucus or amniotic fluid charged with meconium it was necessary to (1) free the air passages, and (2) to facilitate the entrance of air into the lungs. As the mucus frequently only occupied the throat it was often sufficient to clear it out by means of the finger wrapped in a handkerchief. Cutaneous friction with or without alcohol, ether, brandy, eau de Cologne, warm baths, mustard baths, hot or cold baths, were often sufficient to excite respiratory movements. Rhythmical traction on the tongue might set up the respiratory reflex. If these procedures failed it was necessary to commence artificial respiration. Of the various methods available insufflation was the only one that fulfilled the two conditions necessary—viz., to clear the air passages and to facilitate the entrance of air. And, further, the insufflation should be instrumental. The apparatus employed should admit of aspiration of the foreign matters present, and it should not carry into the lungs a quantity of air greater than their capacity. To fulfil these conditions the instrument must be constructed upon anatomical principles. The insufflator formed upon the model introduced by him in 1877 fulfilled the necessary conditions. (1) Its introduction was easy owing to its curve and the shape of its end; (2) its curve assured its remaining in the air passages; (3) it prevented the reflux of air from the larynx; (4) it readily permitted of the aspiration of the fluid and mucus filling the bronchial canals; (5) it was easy to determine whether it was in its right position or not; and (6) the bulb attached permitted only of a quantity of air entering sufficient to distend the lungs without over-distending them.

Definition of a Still-birth.

Dr. F. H. CHAMPNEYS (London) in the next paper gave a definition of "still-birth" and divided the two stages of asphyxia into "apoplectic" and "pale, the worst cases being common when the head came last and therefore not being due to pressure on the head. Asphyxia he defined as an exaggeration of physiological "air-hunger" or "necessity for breathing," and after discussing its mode of production and the causes and consequences of premature inspiratory efforts he narrated some remarkable instances of survival of apparently dead children. The objects of artificial respiration he described as (1) removal of foreign bodies from the air-passages; (2) procuring the patency of the air-passages; (3) excitation of the circulation; and (4) ventilation of the lungs. With regard to ventilation of the lungs he considered only two methods of manipulation efficient—namely, that of Schultze and that of Silvester. The method of Silvester produced unnatural superior costal respiration and was the more powerful. The methods of Marshall Hall and Howard he considered useless for children.

Dr. SCHULTZE (Jena) also read a report on this subject. Asphyxia, he said, of newly-born children was the result of some interference with the placental circulation during the course of labour. It was therefore a species of suffocation. Treatment consisted in putting into action as soon as possible—and this was most important—pulmonary respiration. The venous condition of the blood was in a child born asphyxiated already beyond the normal; it no longer acted as a stimulus to the medulla. The spinal cord could, however, still react to other forms of irritation. One of the best of these was the application of cold. When the condition of asphyxia was still further marked the medulla no longer reacted. It was necessary then to restore its excitability. This result could best be obtained by establishing the pulmonary changes and by stimulating the circulation. By the insufflation of air it was possible to set up normal respiration but this did not improve the circulation. The best methods were those which acting upon the thoracic parietes provoked within the thorax regular variations in the atmospheric pressure. Such methods were those of Silvester, Marshall Hall, or his own method of swinging the infant. His rules for the treatment of such cases were as follows: 1. If the child was blue leave the cord uncut, clear out the mouth, and excite the cutaneous reflexes. If this prove insufficient cut the cord and plunge the infant alternately into cold and then hot water. 2. If the child be pale and flaccid cut the cord, clear out the mouth, and then proceed to artificial respiration. Commence by a forced movement of expiration. There was no better method of clearing the air passages. Repeat the movements of expiration and inspiration from eight to 10 times a minute and then place the child in a hot bath. The artificial respiration might then be repeated if necessary. If natural respiration be established but remain superficial plunge the child into cold water. A child born asphyxiated should not be considered as completely re-animated until it cried continuously and vigorously.

GYNÆCOLOGY.

The Treatment of Cancer of the Uterus.

Dr. RICHELOT (Paris) read a paper upon this subject. Total extirpation of the uterus by the vagina was, he said, a rational method, because it enabled them to deal completely with the disease and to get entirely beyond its limits. It was a relatively benign operation, the mortality of the reporter amounting to about 6 per cent. It was an efficacious operation. Ott had had cures extending over 12, 11, 10, eight, and six years; Landau after nine and a half, eight, seven, six, five, and four years; Ledentu and Pozzi after six years; Quénu, Terrier and Hartmann, and Routier after five years. The speaker had had cases alive 12½, 12, 10, nine, eight, six, four, and three years after operation. Making all allowances he was able to show at least 18 per 100 who had been definitely cured. The improvement that had occurred in technique had lead to a revival of the operation of abdominal hysterectomy. Equally to be condemned were those surgeons who advocated extensive operations of this kind both for cases of cancer where the disease had spread beyond the uterus and those who recommended them in cases where the disease was still limited to that organ, with the proviso that in either case such an operation enabled them either to remove all the affected tissue or to make sure of being well beyond the limits of the disease. No true comparison could be made between cancer of the breast and cancer of the uterus and it was impossible even by such an operation as abdominal hysterectomy to make sure of removing all the affected tissues. Cancer was primarily local and secondarily infective. A microbic origin for the disease was as yet unproved. Personally he was led to consider cancer as a trophic lesion independent of external causes. One proof amongst others

was heredity and another the relation between cancer and arthritic troubles. A hundred times he had seen cancer and arthritic troubles transmitted, coinciding or alternating in such a fashion as to convince him as to the pathological family in which they should be placed. And it was the mysterious action of the economy which determined the degree of cellular anarchy, modified its evolution, and settled its prognosis, which enabled them to see things as they really were. It was that which enabled them to combat the evil but at the same time traced out well-defined limits, which ensured their success or their failure. One knew how remarkably variable was the course of a cancer of the uterus. Another remarkable fact was the well-known better prognosis in the case of a cancer of the body of the uterus. In brief, it might be said that a cancer of the uterus passed through two periods, while it still remained limited to the uterus, and when it had passed beyond its limits, and that the duration of these two periods was influenced by some unknown condition, possibly some "morbid temperament." What, then, should be their aim? Undoubtedly to operate at a time when no cancerous cell had progressed beyond the limits of the uterus. If they succeeded in doing this and in removing all the morbid growth then they might well speak of a definite cure, and they might even neglect the predisposition of the organism to reproduce another cancer. The proper treatment of cancer at the present day was to anticipate its spread and not to attempt to overtake such spread once it had begun. And, indeed, the organism itself came to their assistance. Intervention was not always without avail even when it appeared to be a little late. Such cases were difficult to recognise. It was justifiable, however, to adopt the abdominal operation in the presence of a limited spread of the cancer to the vaginal wall, rendering a vaginal operation impossible, but not indicating any real diffusion of the cancer. The operation was also justifiable in the presence of a tumour of slow growth the course of which they had been able to follow for some time. In such cases he had adopted abdominal hysterectomy without regarding it as a sovereign remedy and duly recognising its limitations. He had endeavoured to show that vaginal hysterectomy was capable of obtaining definite cures and that abdominal hysterectomy was a useful resource in a small number of cases, but that applied to cancers which had already become diffused it was an imprudence, and to cancers still very limited an illusion. That was to say, he differed from those who saw in the first an operation always incomplete, merely palliative, and in the second, the only operation which removed all, the only operation which was logical and rational. He would say that that operation was truly curative which preceded the cancerous infiltration—that which pretended to pursue it was really merely palliative.

Dr. DMITRI DE OTT (St. Petersburg) came to the following conclusions on the same subject:—1. Surgical treatment was the only successful method of combating cancer of the uterus. 2. The peculiar functions and structure of the uterus required a special study of the cancers that attacked it. Conclusions drawn from cancer in other parts of the body were only applicable in certain special cases. 3. Total extirpation of the uterus should be practised in all cases of cancer of any part of the organ, since the procedure gave the greatest amount of success. Removal of the ovaries and appendages should only be practised under special conditions. Removal of the retro-peritoneal glands could only be carried out by the abdominal route. This method should not be practised as a rule since it was much more dangerous and the results were not sufficiently good. Total extirpation by the vagina was to be preferred to all other methods. Morcellement in the cases where the uterus was of large size or the case complicated by the presence of fibroids was a method of great value. In cases of pregnancy complicating cancer of the uterus vaginal extirpation should still be carried out. The operation could be practised up to the seventh month and after opening the *cul-de-sacs* and ligaturing the uterine arteries the size of the organ could be readily reduced by the removal of the ovum. If the pregnancy was still further advanced and the child viable the latter might be delivered by abdominal section and the uterus, if practicable, removed by the vagina. It was best not to close the peritoneal opening but to lightly plug it with iodoform gauze. The ultimate results of operation undertaken for cancer of the body were much better than those undertaken for cancer of the cervix. Total extirpation should be practised even in advanced cases, since it tended to alleviate the condition of the patient, and especially in view of the difficulty of making an exact diagnosis of the extent of the disease. The mortality of the operation should not exceed 2 per cent. and the proportion cured with no sign of recurrence after six years was 10 per cent., extirpation having been practised even in the most advanced cases.

Dr. THOMAS S. CULLEN (Baltimore) then briefly referred to the gradual improvement in the operation for carcinoma of the uterus, commencing with amputation of the cervix as practised by Schroeder and his contemporaries, abdominal hysterectomy as recommended by Freund, the catheterisation of the ureters as employed by Pawlick and Kelly, and the more radical operation consisting in the removal of the iliac glands as advocated by Ries, Rumpf, and Clark. He then pointed out the danger of implanting carcinomatous into healthy tissue, as was very likely to occur when the radical operation was performed. He described in detail the operation as performed by Werder of Pittsburgh. In this operation the chances of implanting carcinomatous tissue were reduced to a minimum. The various stages in the abdominal operation, where the cancer was limited to the cervix, he described as follows: (1) removal of broken-down carcinomatous cervical tissue, preferably a few days before; (2) insertion of ureteral bougies if desired; (3) ligation of the ovarian vessels and round ligaments; (4) freeing of the bladder from the uterus and broad ligaments; (5) opening of broad ligaments and freeing of the ureters to the points at which they enter the bladder; (6) ligation of the uterine vessels near their points of origin; (7) and (8) dissection of bladder free from vagina and rectum; (9) removal of pelvic lymph glands; (10) freeing of vaginal fornices; (11) closure of pelvic cavity by uniting the vesical peritoneum with that of the rectum, an assistant meanwhile making strong traction on the cervix from below; (12) closure of the abdomen; (13) ringing of the vaginal vault with a thermo-cautery or knife, thus freeing the uterus and its surrounding vaginal mucosa; and (14) application of a light gauze pack to the space left in the vaginal vault. Thus the uterus was freed on all sides, the vagina dissected loose from the bladder and rectum, and the pelvic and abdominal cavities closed before the operator came in contact with the carcinomatous cervix. Even then there was little or no danger of transplantation of carcinomatous tissue. The speaker then briefly analysed 176 cases of carcinoma of the uterus occurring in the Johns Hopkins Hospital during the last six years.

Cervical Metritis.

Dr. S. POZZI (Paris) read a paper introducing this subject. His conclusions were as follows:—1. Acute or chronic inflammation of the cervix could exist for a long time isolated and without invading the body of the uterus. 2. At times the acute lesions of the cervical mucous membranes readily invaded the mucous membrane of the body, and the chronic lesions of the cervical parenchyma of inflammatory origin (sclerotic or sclero-cystic degeneration, partial or total) in a short time produced some effect upon the nutrition and the anatomical condition of the body of the uterus. 3. The operation of trachelorrhaphy was inferior to biconical resection of the cervix and should be abandoned. 4. A large number of acute, subacute, or chronic inflammations of the cervical mucous membrane in nulliparæ were due to insufficiency of size of the external os uteri and the difficulty of drainage that resulted. The most important part of the treatment consisted in restoring by operation to a sufficient extent the patency of the external os.

Dr. DOEDERLEIN (Tübingen) followed, saying that at the present day the causes of the inflammatory diseases of the cervical canal and of the cavity of the body of the uterus were to be found in a microbic infection. Modern bacteriological researches had shown that the external os uteri formed a boundary between a lower part of the genital tract containing micro-organisms and an upper containing none. The alkaline cervical mucus proved destructive to organisms introduced from without and so formed a protection not only to the cervix but to the body of the uterus, the tubes, and the peritoneal cavity. Amongst pathogenic organisms the only two that played any important part in the production of cervical metritis were the gonococcus and the tubercle bacillus. Gonorrhœal infection of the cervix was very common, the means of defence of the cervix being unavailing against the gonococcus, but tuberculous infection limited to the part was very rare. Tuberculous, syphilitic, and diphtheritic lesions of the cervix were quite different from so-called cervical metritis. Tuberculosis

of the cervix played an important part in the production of cervical metritis. The mucous membrane of the cervical canal was disposed to hyperplasia, the formation of polypi, and to inflammatory induration or erosions. The mucous membrane of the vaginal portion was disposed to changes in the epithelium, that was to say, to papillary and follicular erosions. The etiology of cervical metritis demanded further study both from the bacteriological or clinical point of view.

Dr. MENDES DE LEON (Amsterdam), speaking on the same subject, said that the pathological lesions of the neck of the uterus, which were known as cervical metritis, were difficult to separate clinically from chronic inflammation of the body of the uterus and especially from chronic inflammation of the mucosa. One might distinguish two varieties, the form due to bacteria and that not due to bacteria. In view of the great difficulty in determining the etiology of the chronic form it was best to distinguish them by their clinical signs, and to speak of a catarrhal endometritis or of a pseudo-endometritis, the catarrhal form being characterised by the presence of leucocytes in the stroma, and the pseudo-endometritic form by an abundant glandular proliferation and augmentation of the stroma. It was only in the gonorrhœal and septic inflammations that one saw the inflammatory process penetrating into the substance of the uterus and so leading to a true metritis. In the etiology of non-infectious conditions of the endometrium hyperæmia of long duration played a most important part. With regard to the septic and specific inflammations of the uterus their origin was to be found in the presence of organisms of various kinds which had found their way into the uterus either during the puerperium or through some lesion the result of an operation, or even in the case of certain specific organisms through the intact mucous membrane. With regard to the question as to whether a cervical metritis could remain limited to the cervix or not there was some divergence of opinion. In 100 cases examined with Dr. Van Tussenbroek he found only nine cases of simple cervical catarrh. On the other hand, he found 55 cases of catarrh of the body, of which 39 were circumscribed and 16 combined with cervical catarrh. It was difficult to demonstrate or to exclude the presence of any affection of the body. In the absence of erosions and when there existed a more or less abundant mucous or purulent secretion it was almost certain that they had to do with a catarrh of the body. Athough as regards etiology, &c., the two conditions were to be considered separately, it was not so with the treatment. Here, since the mucous membrane of the body was usually also affected, the common form of treatment was curettage. Amputations of the cervix alone appeared irrational, since this could have no effect upon any accompanying condition of the body of the uterus. In conclusion, he might say that it was necessary neither to consider nor to treat cervical metritis as an isolated affection, since in the great majority of cases it was accompanied by a similar condition of the body of the uterus. The term "cervical metritis" should be replaced by that of "cervical endometritis," since the inflammation of the mucous membrane was rarely accompanied by any lesion of the deeper tissues.

V.—STATE AND MILITARY MEDICINE AND SURGERY.

MILITARY MEDICINE AND SURGERY.

Lesions Produced on Man by Projectiles of Reduced Calibre.

Dr. L. A. LAGARDE (New York) read a paper in which he referred to the early history of reduced calibre rifles, the experimental evidence upon animate and inanimate objects by the surgeons of the different Governments while contemplating a change of armaments, and the general conclusions based thereon. He noted the results of gunshot wounds by the projectile of the 7-millimetre Mauser rifle in the Santiago campaign; and from such data as the office of the Surgeon-General of the United States Army was able to furnish, he discussed the stopping power, explosive effects, bone lesions, and injuries to the viscera occurring in this campaign.

Surgeon-Major VINCENT, *professeur agrégé* at Val-de-Grâce, read a paper upon

The Etiology and Prophylaxis of Typhoid Fever in Armies in the Field.

Typhoid fever, he said, was a necessary companion of every war and was far more deadly than was the fire of the enemy. The causes which brought it about were the same as in time of peace, but during the progress of a campaign the influence of these causes was very much greater. The predisposing causes were the average age of the soldier; the time of year chosen for military operations—summer or autumn; imperfect feeding and the digestive troubles which resulted therefrom; the inevitable deficiencies as to hygienic conditions as regards both the soldier's body and his clothes; a hot climate, as is the case in colonial wars; the shutting up of troops in camps or besieged towns; a very prolonged war, and the demoralisation of an army when conquered. Overwork was also a most potent factor. The immediate cause was the ubiquitous bacillus typhosus. This bacillus was able to live in a latent condition in the digestive tract and thence under favourable conditions to multiply itself and give rise to the appearance of a spontaneous epidemic. The disease might be transmitted from one man to another, but the most frequent cause was water. Food coming from infected regions could also transmit the disease. Other methods of transmission were flies and dust from infected soil. The necessities of warfare made prophylaxis very difficult. At the beginning of the campaign every man, or at the very least every officer, should be briefly instructed in the principal rules for the prophylaxis of all infectious diseases and especially typhoid fever. During the period of concentration and even during active operations overwork should, as far as is compatible with the needs of war, be avoided. For a colonial war only men of not less than 25 years of age should be chosen. Food should be as good and as varied as possible. Personal cleanliness should be attended to and the hygiene of camps should be carefully looked after. Flies, if possible, should be kept away, and above all, if possible, only filtered or boiled water should be drunk and alcohol should be avoided. Anti-typhoid inoculation, according to the method of Wright, as a special method of prophylaxis did not appear so far to have given very definite results. Troops coming from infected garrisons should, if possible, not camp with others. Sick men should be persuaded to apply for relief at the earliest moment. Patients, if seriously ill, should be treated in a special hospital. Disinfection or sterilisation of everything that came from, or had been touched by, the patient should be carried out as far as possible. A camp should not occupy the same place for a long time, and if the fever spread the camp should be abandoned.

Dysentery.

Dr. ANTONY, professor at Val-de-Grâce, read a paper upon the Treatment of Dysentery in Armies in the Field. He said that as they were ignorant of the nature of the germs of the disease secondary causes were of very special importance, such as climatic conditions, atmospheric variations, fatigue, overwork, infection, and contagion. In time of war all these causes were at work simultaneously. War exposed an army to suffering and privation of every sort. The men had to undergo exposure often without any shelter and even the most prudent commander could not always avoid overworking his troops. The food of an army could be carefully attended to except under two conditions—viz., during a siege or a retreat, in both of which the troops were exposed to very cruel privations. A wise administration would always feed an army as plentifully as possible and whenever it could be done with fresh food. The regular rations should not, as a rule, be composed entirely of preserved food. All excess should be severely prohibited. The providing of good drinking water for the troops was one of the most difficult matters to carry out in the course of a campaign. Various methods of purification had been employed, but the best way, and the most certain where it could be done, was to boil the water. In hot countries where dysentery and malaria were particularly frequent and very serious, besides these precautions troops should, if possible, not be allowed to fight during the period of the year in which these maladies were specially prevalent, and the men might also be treated with quinine as a preventive method.

Surgeon-Major SIMONIN, *professeur agrégé* at Val-de-Grâce, read a paper upon the Etiology of Dysentery in Armies in the Field. Dysentery had, he said, from all time been the inseparable companion of armies in the field. The history of ancient and mediæval wars, as well as those even of the most recent times, showed that this disease was the most constant factor in the death-rate of troops wherever they were fighting. The disease was very fatal both in temperate climates and in hot countries. The pathological

agent of dysentery had not yet been absolutely discovered, but at the present time it seemed probable that the disease called "dysentery" represented a collection of pathological conditions. Some observers said that the cause of dysentery was a certain animal parasite—viz., an amœba. Other observers put it down to some particular kind of microbe. Other observers, again, considered that the disease was due to both the microbe and the amœba. Whatever be the cause, the general tendency of modern opinion was to consider that the active agent in the production of dysentery was something common to the human economy which acquired under certain circumstances a power of growth and special virulence. They could, therefore, say that the disease proceeded from ordinary causes which affected the organism and allowed an abnormal development of germs which in the ordinary way were inoffensive. In all infectious diseases the importance of secondary causes was great, but in the case of dysentery the secondary causes were of the very highest importance, and in the case of armies in the field these influences were so many in number that they must study them in some methodical fashion. First of all there was the influence of climate and of the different seasons of the year. Heat, for instance, tended to make dysentery the special malady of troops operating in tropical countries. The influence of variations of temperature, and in particular the sudden chilling of the body, played a considerable part in bringing about attacks of diarrhœa and dysentery. A very important cause of dysentery was the influence of food of bad quality and the prolonged use of bulky or indigestible food. Intemperance, whether in food or drink, and above all in a tropical climate, had been rightly said to be a cause of dysentery. Scarcity of food, on the other hand, was also capable of producing the same effect. The fatigue and overwork which were inseparable from warfare and the accumulation in the organism of fatigue-products diminished the resistance of the body and favoured the attack of the dysenteric germs. After a war had lasted a certain time a new factor arose—viz., pollution of the soil and to a certain extent of the air. This cause arose chiefly in camps and besieged towns mainly from the accumulation of various dirty liquids and waste matters and the bodies of men and animals. When dysentery had once made its appearance under the form of a frequent diarrhœa it spread very rapidly through the army, mainly by the influence of water and of soil and of the dust of places which had been definitely polluted by the dejections of the patients. In temperate climates dysentery was generally associated with typhoid fever and in tropical climates with malaria.

The Prophylaxis of Syphilis in the Army.

Surgeon-Major FERRIER, *professeur agrégé* at Val-de-Grâce, and Dr. PANARA, the delegate of the Minister of War for Italy, read papers upon this subject. The chief means which they laid down as being effectual were (1) the giving of regimental instructions on the subject to the officers and non-commissioned officers by the medical officers, which instructions should then be handed on to the privates; and (2) the preparation of a little book for the privates containing the simple rules of hygiene. The moral level of soldiers should be raised in every possible way. M. FERRIER said that he was very pleased to see that in the French army fewer permissions were granted to soldiers to go to the theatre or to be out for one night, but that there was an increase in the number of permissions given to men to return to their homes for a certain period of time. Finally, he considered that the temperance campaign would do a great deal of good. Dr. PANARA considered that the chief method of prophylaxis must be treated as a question of public order and rules which affected only the barrack or the hospital could but treat the matter in a secondary way. He agreed with M. Ferrier as to the good which might be derived from the giving of regimental lectures, and he advised that a strict system of surveillance should be carried out in every regiment and barrack. Men should not be punished or reprimanded for applying for relief in cases of this complaint.

Extemporaneous Methods for the Purification of Water.

Surgeon-Major LAPASSET read a paper upon this subject. He pointed out that water was absolutely necessary for the soldier, and therefore in default of a good supply of drinking water it was necessary to make use of water which was more or less of a bad quality, and this had to be purified before use. The simplest method of purification was by boiling, but this method was almost impossible to carry out for an army in the field. Another method was filtration, and various filters, such as the Chamberland or the Berkefeld, gave good results. Carbon filters were dangerous to use because they got so quickly infected. Another method of purification was by means of chemicals such as permanganate of potassium. If possible, whatever be the method of purification employed, it should be under the control of an officer who should preferably be a medical officer. Any apparatus used should be a collective apparatus, and not one which was under the control of an individual.

Surgeon-Major SCHUCKING spoke on the same subject. The two chief methods of purification which he considered were filtration and purification by some chemical agent. For troops in the field, if they were in close connexion with the base, filters acted very well, but if the troops were far away from their base chemical agents were more easily employed, such, for instance, as the hyperchloride of lime.

Dr. VINCENT, *médecin de bataillon*, followed on the same subject, treating the subject with special reference to the purification of water for troops on the march. The best system, in his opinion, was that of chemical purification after the method employed by Lapeyrière. In default of this the water might be boiled.

Tropical Phagedæna.

Dr. LE DANTEC (Bordeaux), a first-class naval surgeon, read a paper upon this subject. He pointed out that in hot countries any wound of the skin rapidly passed into a state of ulceration, and that this ulceration exhibited the condition known as phagedæna, which was remarkable for its tendency to invade healthy tissues. Phagedæna appeared to be due to a bacillus which closely resembled that described in 1896 by Vincent as occurring in Madagascar. He himself had discovered this bacillus in the year 1884. The natural home of the bacillus appeared to be damp ground.

The Care of the Wounded in Naval Warfare.

Dr. FONTAN, a French naval *médecin en chef*, read a paper on this subject. They were met, he said, at the outset by the question whether the surgeon could really do his work during the progress of the fight. In France it was considered that the surgeon could not go among the wounded so as to bring them aid on the spot where they fell. He had to remain in the place which was appointed for the reception of the wounded. But could the wounded be taken to this place at every moment of the fight? Unfortunately no. It almost invariably happened that before the wounded could be moved they had to wait for the fire to slacken, and in the meantime they had to remain where they had fallen exposed to the risk of receiving a new wound without any care, and very possibly liable to die from loss of blood or from shock. These conditions could be ameliorated to some extent by instructions given to the combatants before the fight began, together with a packet of first-aid dressings. These things, together with a plentiful supply of tea with a slight admixture of alcohol, should be within the reach of all the fighting men. Supposing, however, that the time for moving the wounded had arrived, it was very difficult on board ship to move a wounded man to the appointed place where the surgeon was at work without harming him, and the best method of doing this was the use of the metal stretcher splint of Auffret. This moulded itself around the body of the wounded man, it kept him absolutely at rest, and it passed easily through very narrow passages. Once the wounded man had arrived at the place where the surgeon was stationed he was placed on the operating table and the first thing to be done was to render his wounds as aseptic as possible. This could be done by irrigation with boiled water, by the application of certain antiseptic solutions, and by dressings of antiseptic gauze. If the dressings were carefully packed in sealed parcels sterilisation in a stove was only indispensable in the case of instruments and of sutures. Bleeding must be stopped, and the loss of blood could be supplied by injections of boiled water to which a little salt had been added. Fractures should be put up in splints, and urgent operations must be undertaken, such as the ligature of arteries, the putting up of fractures, and the closing of cavities of the body which had been opened. A search for foreign bodies should always be postponed. All this treatment, however, should be simply provisional. The wounded should be landed as quickly as possible, or else transferred to a hospital ship. It was quite time that civilised nations should add to their fleets of war

a hospital ship flying the Red Cross, which could, after the battle, collect the wounded of its own nation.

Hospital Ships.

Dr. BUROT, a French naval *médecin en chef*, read a paper on the Use of Hospital Ships. He had served in the expedition to Madagascar in 1895 and came to the following conclusions :— 1. Any ship destined for use as a hospital ship should be specially fitted for that purpose. 2. It was absolutely certain that in very malarious countries situated under the torrid zone it was much better when it was possible to treat the sick and wounded on a hospital ship rather than on land. 3. For a hospital ship to render the greatest amount of service it must be a hospital ship and nothing else. 4. In the case of a war lasting for a long time it would be as well to provide at the base of operations a floating hospital large enough to put up all the sick and wounded of the expeditionary column, and at the same time to organise a fleet of quick-steaming transports specially fitted up so as to carry the wounded back to their own country. 5. A floating hospital should be able to hold at least 500 patients. Ventilation should be carefully looked after, and if this could not be done by natural means electric fans should be employed. Distilled water alone should be used, but if the apparatus was not extensive enough to give a constant supply filtration might be employed instead. The question of ice-making on board ships had not yet been finally settled, but the apparatus which gave the best results was that which worked by compressed air. 6. The most serious inconvenience on board the hospital ship occurred in the presence of infection. It was almost impossible to obtain complete isolation on board a ship, and in view of the possible occurrence of infection it would be as well to fit out, at some little distance from the hospital ship, a smaller vessel which could serve as an isolation ward.

Plague.

Dr. SIMON and Professor YERSIN read a paper on Epidemics of Plague in the Far East. These observers were of opinion that plague did not arise in any place by itself, neither did it reappear, unless it was re-imported, after a lapse of 20 years. This fact had been established by the epidemics which occurred at Constantinople, Venice, Genoa, and Messina in 1347 when the plague was imported from Jaffa, by the epidemic in Marseilles in 1720, when it came from Syria, and by that at Kutch Mandvi in 1812, when it came from Mecca. The study of recent epidemics led them to the same conclusion. They laid down as first principles (1) that plague spread from a centre in the same way as a drop of oil, that was by circular extension ; (2) that the plague could be carried from the primary centre to a distant point if there was direct and rapid communication between those points ; and (3) that contamination of distant centres was exceptional except when they were connected with the principal centre by railways or shipping lines. In the Far East plague spread from endemic centres by means of trade routes. Its march, however, was very slow, and neighbouring regions, if separated from the centre of infection by natural barriers, escaped ; thus, for instance, Yunnan in China had not affected Tonking. It was from Yunnan that the germs had gone out which were at present spreading throughout the whole world. It took 30 years, from 1850 to 1880, to attack Long-Tcheou and Pakhoi by following the course of the rivers and the various lines of communication. In 1893 English diplomacy procured the opening of the Canton river to trade. The plague started from Long-Tcheou, overran Canton and Hong-Kong, and in four years' time it was spread throughout the four quarters of the world. It was useless to discuss the origin of the plague of Bombay but it might profitably be considered how the plague passed out of India. The port of Kutch Mandvi would appear to be the point of departure. The sanitary police of Bombay and at Karachi did their work admirably, but, on the contrary, at Kutch Mandvi, where there were no Europeans, both entrance to, and exit from, the port were practically free. This port, however, was in constant relation by means of small sailing ships with Madagascar, Zanzibar, Mauritius, Jeddah, and the Persian Gulf. A cultivation of the plague bacillus which had been obtained by Yersin and Carré which killed 20 per cent. of rats that had been inoculated with it and which they called the bacillus C was next referred to. Perfect immunity was obtained in animals by inoculating with this bacillus after a period of 15 days, but experience of the method was still wanting to enable an opinion to be pronounced as to whether this immunity was lasting. Dr. Yersin had inoculated himself without any ill-effects except a slight rise in temperature.

Tetanus.

Dr. F. CALMETTE (Lille) read a paper upon the Prophylaxis of Tetanus in Hot Countries. He pointed out that tetanus was very frequent in the torrid zone, more especially on the West Coast of Africa, in Guiana, and in the Antipodes. Young children were especially affected by it, and in Indo-China many newly-born children died from it. The black races were the most easily affected, the white races took the second place, and the yellow races took the third. The infection of tetanus in hot countries arose almost always from the soiling of wounds by earth or by the dejection of animals. Tetanus in new-born children arose from an infection of the umbilical wound. The best measures of guarding against tetanus were as follows :—1. To spread throughout the colonies in hospitals, in ambulances, and in columns of troops on the march the use of anti-tetanic serum so as to prevent tetanus occurring in those whose wounds were infected either with dirt or with portions of clothing. In every case of gunshot-wound, after the first dressing had been applied, a preventive injection of 10 cubic centimetres of anti-tetanic serum should be given. 2. Throughout tropical colonies native women, both mothers and midwives, should be educated with regard to the elementary precautions necessary for women and their newly-born children. Lectures should be given in every colonial centre where there was a medical man at which simple instructions should be given with regard to the dressing of the umbilical cord, on the proper treatment of which the prevention of tetanus in newly-born children almost entirely depended.

Papers were also read by Dr. FIRKET (Liège) and Dr. CLARAC upon the Etiology and Prophylaxis of Bilious Hæmoglobinuric Fever in Hot Countries and by M. E. MARCHAUX upon the General Etiology and Prophylaxis of Hæmoglobinuric Affections.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT IPSWICH.

THE occasion of the meeting of the British Medical Association at Ipswich was utilised by the Irish Medical Schools' and Graduates' Association to hold their annual summer meeting at the Higher Grade School, Ipswich, on August 1st. In the absence of the President (Inspector-General Lloyd, M.D. St. And., R.N.) the chair was taken by Dr. H. Macnaughton Jones, ex-President. There was a large attendance of members, including Sir John W. Moore (Dublin), President of the Royal College of Physicians of Ireland, Professor W. H. Thompson (Belfast), Professor R. J. Anderson (Galway), Dr. W. J. Smyly (Dublin), and the provincial honorary secretary, Mr. James Stewart (Clifton). The Council reported the completion of the arrangements in reference to the Arnott Gold Medal which has been given by Mr. David Arnott in memory of his late father, Sir John Arnott, Bart., and which is to be awarded annually to such Irish medical graduates or diplomates as shall be decreed by the Council to have pre-eminently distinguished themselves by some act of heroism in civil, naval, or military life, or by some achievement in medicine, surgery, or medical research. The chairman, in referring to this generous gift, stated that Mr. David Arnott had most courteously complied with all the requests of the Council in reference to the legal details of the deed by which the medal had now been permanently endowed. He (the chairman) wished to emphasise the fact that those qualified for the distinction were not to be confined to members of their Association and that the medal might be awarded to any Irish medical graduate or diplomate whom their Council might adjudge worthy. The first award would probably be made before the next festival dinner. Sir John W. Moore, having remarked on the warm liberality and patriotism displayed by the son of the late

much esteemed Irishman, Sir John Arnott, in this matter and above all on the evidence which it afforded of the high estimation in which the donor held the medical profession generally, and especially the *alumni* of the Irish schools of medicine, concluded by moving: "That the heartiest thanks of the association be, and are hereby, accorded to Mr. David Arnott for his generous gift of the gold medal endowed by him in memory of his late father, Sir John Arnott, Bart." Dr. Dolan seconded the motion, which was carried with acclamation. The provincial honorary secretary having stated the views of the Council on the question of restriction of honorary appointments in certain English hospitals to the diplomates of two specially favoured colleges, and having given a *résumé* of what had already been done in the way of abolishing such out-of-date monopoly so antagonistic to the "open-door" spirit of the times, Dr. Douglas proposed, Dr. Esler seconded, and it was carried unanimously: "That this meeting hopes that the Council will as soon as possible proceed actively with their efforts to reduce the number of English public hospitals in which the Fellows (by examination) of Irish colleges are not now eligible for honorary appointments on the staff." It was announced that the Association had determined to entertain Field Marshal Lord Roberts on his return from South Africa at a special banquet to be held in London, the date to be probably in the last week of November. A vote of thanks to the chairman terminated the proceedings.

The collection made at the opening service at St. Mary-le-Tower was stated last week to be destined for the British Medical Benevolent Fund. We learn that this fund receives half the collection, the other half being given to the Royal Medical Benevolent College, Epsom.

On the evening of Wednesday, August 1st, Mr. W. A. Churchman, the Mayor of Ipswich, received the members of the British Medical Association at a garden fête held in the grounds of Christchurch House. This beautiful old Elizabethan mansion belongs to the town, but on the above evening the general public were excluded. The grounds were illuminated by Chinese lanterns and small oil lamps while the windows of the front of the house were outlined in the same manner. Music was provided by the band of the Norfolk Regiment and the evening being beautifully fine the fête was a great success. During the evening a firework display was carried out under the direction of Mr. Paul Aggio of Colchester. The set piece showed the words "Welcome to the British Medical Association," the letters appearing in changing colours. Altogether the entertainment was a great success.

On the afternoon of the same day a garden party was given by Mr. Felix Cobbold of The Lodge, Felixstowe. Some 300 guests were present. Music was provided by the band of the Brantham Works augmented by some players from the Ipswich Artillery Band. The magnificent conservatories and hothouses were seen at their best.

On Thursday, August 2nd, members were invited to a garden party given by Captain and Lady Beatrice Pretyman at Orwell Park, and in the morning Mr. J. S. Corder conducted a party over Christchurch mansion and the Ancient House, besides demonstrating sundry other of the antiquities of Ipswich, such as Wolsey's Gateway.

The annual dinner of the Association was held on the evening of Thursday in the Town-hall. In addition to the President and the other officers of the Association there were present the Mayor of Ipswich, the High Sheriff of Suffolk, Sir Charles Dalrymple, M.P., Professor Simon Flexner of New York, Professor Nicolaysen of Christiania, Professor John Berg of Stockholm, Professor Lenader of Upsala, Professor Thoma of Aix-la-Chapelle, and some 250 members. After the usual loyal toasts the High Sheriff of Suffolk proposed "The Navy, Army, and Imperial Forces." The substitution of the word "imperial" for the usual one of "reserve" was significant of the knitting together of the empire by recent events. The responses, however, were given in the usual manner. Surgeon-General J. B. Hamilton responded for the army, Inspector-General A. Turnbull, R.N., for the navy, and Lieutenant-Colonel Andrew Clark for the reserve forces. Other toasts were "The Mayor of Ipswich," proposed by Sir John Moore; "The British Medical Association," proposed by Sir Charles Dalrymple, M.P.; "The President," proposed by Dr. Pye-Smith; and "The Guests," proposed by Dr. Buzzard. During the evening a reception was held by the ladies of the East Anglian Branch in the Museum.

THIRD GENERAL MEETING.

The third general meeting was held in the Central Hall of the Higher Grade School on August 2nd.

The PRESIDENT called upon Mr. FREDERICK TREVES to deliver his address in Surgery. This address was published in THE LANCET of August 4th, p. 312. At the conclusion of the address, which was most cordially received, a vote of thanks was moved to Mr Treves by Mr. T. R. JESSOP (Leeds) and seconded by Dr. WARD COUSINS. MI. TREVES briefly returned thanks.

Dr. ROBERTS THOMSON, the President of the Council, then rose to present to the meeting the list of the names of those who had been nominated by the Council that morning to serve on the committee to consider the reconstitution of the Association. These were:—for South Africa, Surgeon-General J. B. Hamilton; for the East Indies, Mr. James Cantlie; for Ireland, Sir John Moore; for Scotland, Dr. J. C. McVail; and for England. Dr. Roberts Thomson, Dr. Radcliffe Crocker, Mr. T. Jenner Verrall, Dr. R. Saundby, Dr. S. Woodcock, Dr. Ward Cousins, Mr. H. T. Butlin, and Mr. Andrew Clark.

Mr. Horsley's nominations were as follows:—For the West Indies, Dr. C. G. Gooding, late of Barbados; for Australasia, Mr. C. G. D. Morier of Adelaide; for Scotland, Dr. R. C. Buist of Dundee; for Ireland, Professor J. W. Byers; for Canada, Mr. Edmund Owen; for England, Dr. A. Cox of Gateshead, Dr. William Gordon of Exeter, Dr. C. H. Milburn, Dr. A. G. Bateman, Dr. A. B. Ritchie, Mr. J. S. Whitaker, and Mr. Victor Horsley.

Dr. BERNARD O'CONNOR said that in accordance with the rules observed in the appointment of a Royal Commission the Association ought to select a chairman of the committee. That being so he proposed Mr. Victor Horsley.—This was seconded by Dr. ALFRED COX, but the CHAIRMAN said that he must rule the motion out of order.—The nominations were accepted *nemine contradicente*.

Dr. SARAT K. MULLICK rose to move the following:

(1) The present system of filling professorial chairs in the medical colleges in India, by virtue of grade rank in the Indian (Military) Medical Service, is apparently prejudicial to the interest of medical education and sanitation, and is a sinister bar to the advancement of original research in India. This meeting is of opinion that some change is necessary, and hereby appoints a sub-committee to consider the matter and report to the Council such action as it may think it proper to take.

He remarked that in deference to representations which had been made to him he had modified the terms of his motion. He continued in a well-argued speech to contend that some inquiry ought to be made, as he did not consider that his statements should be taken on his word alone.

Colonel KENNETH MACLEOD, I.M.S., while sympathising with the mover of the resolution, opposed it on the ground that it really involved an inquiry into the whole system of the government of India. After a few words from Dr. CHOWRY-MÜTHU it was eventually decided to refer the matter to the Standing Committee of the Parliamentary Bills Committee.

Mr. VICTOR HORSLEY had given notice that he would move—

That the Council be, and hereby is instructed to allot the sum of £300

for the travelling and hotel expenses of the provincial members of the committee mentioned in the foregoing motion.

This referred to the committee on the constitution.

Mr. Horsley's motion was seconded by Dr. WOODCOCK, but was finally altered so that no definite sum was mentioned, but it was agreed that provincial members should be allowed one guinea per diem for hotel expenses as well as their travelling expenses.

The meeting shortly afterwards adjourned.

FOURTH GENERAL MEETING.

The concluding general meeting was held on August 3rd in the Central Hall of the Higher Grade School at 2.30 P.M.

The PRESIDENT read a telegram which he had received from Osborne in reply to the message of sympathy with Her Majesty passed by the Association. He then called upon Dr. WILLIAM SMYLY to deliver his address in Obstetrics. The address, of which the subject was Maternal Mortality in Childbirth, will be found at p. 385.—A vote of thanks to Dr. Smyly was proposed by Professor BYERS and seconded by Dr. W. S. A. GRIFFITH.—Dr. SMYLY having replied, the PRESIDENT read out three resolutions which had been sent up from the sections. One from the section of Obstetrics dealt with the notification of puerperal fever. Two sent up from the section of State Medicine dealt with the subject of the housing of the working classes and with the use of food preservatives. These were unanimously referred to the Council.—The customary votes of thanks to the Mayor of Ipswich and others who had assisted the Association in various ways were then put and carried unanimously.—A vote of thanks to Dr. ELLISTON, the President, was proposed and carried by acclamation and the meeting terminated.

THE SECTIONS.

MEDICINE.

THURSDAY, AUGUST 2ND.

The Problems of Gastric Ulcer.

Dr. J. F. PAYNE (London) opened the discussion on this subject. He referred to the imperfection of their knowledge with regard to this affection. He had little doubt that it was becoming increasingly prevalent. In proof of this assertion he gave statistics of the number of cases of gastric and duodenal ulcer admitted into St. Thomas's Hospital in the six quinquennial periods from 1870 to 1899 and they were respectively 30, 38, 70, 103, 174, and in the last period —i.e., 1895–1899—216, or five times as many as they were 20 years ago. When allowance had been made for the fact that many cases were now sent in for operation that would probably not have been at the earlier period and also for other accidental causes of increase in the number of admissions, he still was convinced that these corresponded with an increase of the disease among the general population. Gastric ulcer shared in this respect with other digestive diseases. Thus among the continued fevers, enteric fever, a fever characterised mainly by a digestive lesion, had supplanted typhus fever, a fever of more general character, and there was a real increase in the number of cases of typhlitis or appendicitis. As to diagnosis, was it always complete and satisfactory? The principles upon which it was based had been long well known. The three cardinal symptoms were pain in the epigastrium of a peculiar character, vomiting or gastric irritability, and hæmatemesis or melæna. Age incidence was also important. Only one diagnostic sign had been added in the last 30 years—hyperacidity of the gastric juice. As to the peculiar pain he found it present in a decided minority of cases, and in some pain was not present at all. Vomiting was present in most cases. As to hæmatemesis, he had been surprised to find that out of 48 fatal cases it had occurred in only 14, while in non-fatal cases it had been present in 95 per cent. of cases under his own care and in 75 per cent. of all cases in the hospital. His explanation of this discrepancy was that many cases proved fatal by perforation, in which complication hæmorrhage was known to be uncommon, while non-fatal cases were often sent to hospital on account of that very symptom. In his opinion it was the most reliable of the above signs. Other causes of hæmatemesis were alcoholism and cirrhosis of the liver, aneurysm rarely, and direct injury or strain. In this connexion he mentioned three cases in which hæmorrhage appeared to have originated the ulcer. Hæmatemesis in men was most frequently due to cirrhosis of the liver, in women to gastric ulcer. He knew little practically about hyperacidity of the gastric fluid, as he had never been able to think that it was a justifiable proceeding to put a tube into a stomach which was the seat of ulceration. Dr. Payne then discussed the differential diagnosis between acute and chronic ulcers. Acute ulcers were those where the symptoms developed rapidly. In 48 necropsies six ulcers were found to be acute and 42 chronic. Of the cases examined 36 had had symptoms for a long time and 12 for a short time; thus six chronic ulcers had acute symptoms. As to sex incidence Fenwick estimated that the disease was present in 10 females to one male. Dr. Payne found the ratio in acute ulcer to be two to one and in chronic ulcer four and a half to one. He inquired if the classes had the same pathology or if a chronic ulcer were anything else than an acute ulcer grown older. Among suggested causes were digestion, embolism, congestion, poisonous substances, and bacteria. Digestion explained the persistence and chronicity of the ulcer, but they did not know what started the local necrosis. It was usually called a disease of the poorer classes. Had the statement any other origin than their greater relative numbers? As to mortality, more women died under the age of 30 years than women over 30 years, but if the percentage of deaths per person living at the same age was taken more deaths were found at the older periods in both sexes. Post mortem an occluded vessel was often found in the middle of the ulcer. Dr. Payne thought that this proved nothing more than that the hæmorrhage had been arrested by natural means and not that the apparent thrombosis was the cause of the disease. The main principle of treatment was to give rest to the stomach. Rectal feeding enabled this to be done. It was a doubtful point as to whether the rectum absorbed much food. He thought peptonised food the most likely to be absorbed. He always allowed a little warm water to be given by the mouth, but not for the first 24 hours after hæmorrhage. The danger of long-continued rectal feeding was that syncope sometimes came on. He thought that it might be continued safely for 14 days if water by the mouth was allowed and for seven if water was withheld. During the treatment acetone sometimes appeared in the urine; this fact, he thought, proved nothing but starvation and he thought practical starvation was also the cause of the appearance of the same substance in diabetes and chronic alcoholism. In conclusion he submitted the following problems for discussion. Was the disease increasing? Was its diagnosis accurate enough? Was the acute form essentially different from the chronic? Was its original cause known? Was the hyperacidity always present and were they justified in trying to ascertain this? Were the upper classes as much affected as the lower? Should water by the mouth be allowed during rectal feeding?

Dr. S. H. HABERSHON (London) showed two diagrams compiled from cases under the care of the late Dr. S. O. Habershon. Only the cases of patients who had had hæmatemesis or those in which the presence of ulceration had been proved by necropsy were included. They were corrected to the absolute liability of all persons living at the same age and showed that the liability of females to the disease increased rapidly up to the age of 30 years, went down slowly up to 50 years of age, and then fell rapidly to the age of 60 years, while that of males increased steadily from birth to the end of life. Dr. Habershon thought that these showed that there was still some unexplained determining cause in young females. Dr. S. O. Habershon had said that he never felt sure of the diagnosis of gastric ulcer unless hæmorrhage had been present. Difficulties of diagnosis were (1) early cases, (2) neurotic cases with much hyperæsthesia, and (3) those very rare ones in which food relieved the pain. The presence of dilatation of the organ was an assistance to diagnosis in some cases, especially in men and when the ulcer was near the pyloric end. He considered it unjustifiable to pass a stomach tube in these conditions.

Dr. W. GORDON (Exeter) said that no one had ever seen a gastric ulcer in the living body till a few years ago. He had obtained a recent specimen eight or nine years ago which, when examined microscopically, showed a digested edge, next to that an area filled with leucocytes, and deeper still a layer of cells stuffed with cocci. He reviewed the possible causes of the disease—embolism, thrombosis, submucous hæmorrhage, trophic lesion, poisoning in food, mechanical pressure as from tight-lacing, injury to the mucous membrane, and micro-organisms. He considered the last-named to be the most probable and asked that in every case

where a gastric ulcer was excised it should be preserved for the most careful bacteriological and microscopical examination.

Dr. W. CALWELL (Belfast) referred to preventive treatment.

Miss JULIA COCK (London) related two cases which had presented almost all the symptoms of gastric ulcer. The first patient had had severe hæmatemesis and vomiting and subsequently signs pointing to subphrenic abscess. She died from pneumonia and no signs of any lesions whatever could be found in the digestive tract. The second patient had had hæmatemesis and signs of perforation of the stomach. A laparotomy was done and no disease or perforation was found. Eight years after, owing to the persistence of similar symptoms, a second operation was performed. The stomach was found to be healthy but there were chronic peritonitis and many adhesions to the stomach. The peritonitis was probably a relic of the first operation.

Dr. NEWTON PITT (London) considered that hæmatemesis was more often a symptom of other diseases than of gastric ulcer. As the cases of this disease became more frequent in males up to the end of life so he believed would those among females if all those were excluded in which the diagnosis was based on the single symptom of hæmatemesis. He stated that the ulcers found in the stomach in the post-mortem room were nearly always in old people. He had made two necropsies of persons who died from hæmatemesis and had found no ulceration, and, in fact, no cause whatever for hæmorrhage. He thought that it would be as well in the future to call such cases simply cases of hæmatemesis and not gastric ulcer. They were familiar with the engorged state of the gastric mucous membrane produced by the administration shortly before death of ammonia, ether, and brandy and possibly partly by paulo-ante-mortem digestion. Might they not have similar conditions in enfeebled states of the body? Some drugs—i.e., opium—were undoubtedly secreted into the stomach after absorption causing engorgement of the vessels. Might not poisons produced in the intestine by constipation act in the same way and cause hæmorrhage as toluendiamine would do?

Mr. STUART LOW (London) thought that ulceration might be produced by loss of the normal gastric mucus.

Dr. PYE-SMITH (London) drew attention to the great discrepancy between the results afforded by the clinical and the pathological investigation of causes of gastric ulcer as to its age and sex incidence. From clinical evidence they should assert that the greater number of cases were among young women, from post-mortem room records among elderly men. This convinced him that there was much to be learnt as to the pathology of the disease and he hoped that all ulcers excised during life might be examined. With regard to the microbic theory he could only say that "confidence is a plant of slow growth in an aged bosom." While agreeing that arterial embolism was not a likely cause he thought thrombosis of veins a much more probable one. He considered the acute perforating ulcer, as described by Rokitansky, Cruvelhier, and others, very different from the ordinary cases. As to the cases where hæmatemesis was present without ulceration they had epistaxis occurring in young men, hæmaturia in both young men and young women, and why not hæmatemesis without visible lesion? He did not keep up exclusive rectal feeding for more than 24 hours.

Dr. R. SAUNDBY (Birmingham) did not like the popular view of gastric ulcer. He agreed as to the great difficulty of diagnosis, but pointed out that if Dr. Newton Pitt's views were correct they could not diagnose gastric ulcer at all. He never made a definite diagnosis of the disease unless many symptoms were present at once. If diagnosis were so difficult how much more so must be any decision as to treatment. He did not employ rectal feeding unless there was hæmorrhage and then only for from 24 to 48 hours, which was not what was usually termed exclusive rectal feeding at all, and then he gave small doses of the sulphate of magnesium and iron.

Dr. F. M. POPE (Leicester) said that in addition to allowing patients a small amount of water he gave five grains of resorcin in an ounce of distilled water three or four times a day. Whether in that dose it did or did not act as an antiseptic it gave relief to the pain.

Dr. PAYNE, in reply, said that his experience as to the difficulty of diagnosis had been borne out by the discussion. He had seen one case which to some extent supported the bacterial theory. In a post-mortem examination of a stomach two ulcers were found, one recent, the other chronic, which suggested to his mind the possibility that the former had been caused by direct infection from the latter.

Intermittent Pulse.

Professor CUSHNY (Ann Arbor, Michigan) read a paper on this subject. He said that the classification of the varieties of intermittent pulse at present employed was not in accordance with cardiac physiology. He therefore was about to propose a new method. He showed a large number of diagrams and of sphygmographic tracings. Intermissions of the pulse were of several kinds. They might have an auricular contraction without a ventricular; here the ventricle was at fault. The auricular contraction might be delayed; here the auricle was at fault. In the former of these the intermission usually had double the time of a pulse interval; in the latter it might be of any length. In a third variety the ventricle contracted too soon owing to extreme irritability and the subsequent pause was consequently longer than normal. In a fourth the auricle contracted too soon (auricular hyper-irritability). In the third form the pulse was double the pulse interval; in the fourth less than a double pulse interval. In both if the pause equalled two pulse intervals the fault lay with the ventricle and it was less than that with the auricle. In the third and fourth forms the first sound was audible if the heart was listened to. In the first and second forms no heart sound was heard. Professor Cushny explained and illustrated these views by means of his diagrams and sphygmograms and said, in conclusion, that assistance in treatment might result from the general acceptance of his conclusions, as they might expect cardiac stimulants to do good in the first and second forms due to retardation of systole, while drugs like aconite, having a restraining influence, would be more likely to be useful in the third and fourth forms.

Dr. J. BARR (Liverpool) could not accept the conclusions. The auricle was extremely irritable and could be excited to contraction for several hours after death. He did not think that it ever failed to contract and intermissions of the pulse could not be tabulated in that way. He thought that the times of the cardiac systole and diastole were always varying. Many intermissions of the pulse did not correspond to intermissions of the heart. Full contraction of the right side might coincide with imperfect contraction of the left and *vice versâ*. In some cases of fatty heart he believed that the right heart hardly contracted at all, the preliminary circulation being carried on by the aspiratory movements of the thorax and the *vis à tergo* from the systemic circulation.

Professor CUSHNY replied. He thought that the auricle could fail and doubted if independent contraction of the right and left sides of the heart did not occur. Irregularity might be due either to muscular failure or to nervous influence. The latter had been shown in animals after the administration of pilocarpine.

Professor C. R. MARSHALL (Cambridge) gave a short demonstration of Different Forms of Sphygmographs, such as Fick's and Jacquet's, which had a time-marker. The former was more complicated but eliminated error due to inertia of the lever. He also showed a recent form of Sphygmomanometer.

SURGERY.

WEDNESDAY, AUGUST 1ST.

Pyloroplasty.

Mr. L. A. BIDWELL (London) read the notes of four cases of Pyloric Obstruction in which he had performed Pyloroplasty. In one of them a "tumour" was found which was thought to be malignant and so a gastro-enterostomy was performed, but two years later, as the symptoms returned, a pyloroplasty was done and the "tumour" had disappeared. In all the cases recovery followed. He considered that pyloroplasty was the best treatment for non-malignant stenosis of the pylorus. He thought that the operation was useful even when the ulcer was not close to the pylorus. He employed a modification of Halstead's "square suture."

Professor BERG (Stockholm) did not consider pyloroplasty a satisfactory operation, although in 1896 he had published eight successful cases. He found that the stenosis returned after two or three years and therefore he preferred to perform gastro-enterostomy, and of the eight cases mentioned four had required the performance of this operation on account of recurrence.

Dr. C. H. KILNER (Bury St. Edmunds) had operated by

pyloroplasty for stenosis caused by some acid which had been swallowed. Unfortunately, the operation had been left too late, for the patient died from exhaustion although the wound of the pylorus had healed.

Mr. T. H. MORSE (Norwich) wished to know about the suitability of the operation for duodenal ulcer. He had performed it in one case for ulcer of the duodenum but without success.

Mr. BIDWELL, in reply, mentioned that he had found recurrence occur after gastro-enterostomy and therefore had employed pyloroplasty.

Cholecystocolostomy.

Mr. H. BETHAM ROBINSON (London) read the notes of a case in which he had performed this operation. The patient was a man, 33 years of age, who had had syphilis 10 years previously. Four years before he came under observation he had sudden severe epigastric pain and vomiting which recurred. A fortnight later jaundice came on with severe itching. The liver was enlarged and there was a rounded swelling below the liver edge. The paroxysms of pain became worse. An incision in the right semilunar line exposed the gall-bladder, which was much distended, and a hardness was felt in the gastro-hepatic omentum and in the head of the pancreas. This was thought to be malignant and it was decided to connect the gall-bladder with the bowel, but the duodenum could not be brought into contact with the gall-bladder so a junction was effected with the transverse colon. No stone was found in the gall-bladder. The jaundice and itching were rapidly relieved. Some iodide of potassium was then administered and the hardness at the head of the pancreas gradually disappeared, so it was probably gummatous in nature.

Non-malignant Stricture of the Rectum.

Mr. F. C. WALLIS (London) commenced his paper upon this subject by remarking that it was usually taught that syphilis was the common cause of non-malignant stricture of the rectum. He considered that septic ulceration was the real cause. This septic condition might be due to operations for hæmorrhoids or to injury in protracted labour. In many of the cases there was not the slightest history or sign of syphilis. In these cases the routine treatment by bougies was perfectly useless and Mr. Wallis described two cases in which the stricture was completely excised, in one with and in the other without a preliminary colotomy. In both the cases the peritoneal cavity was freely opened. He preferred the previous performance of colotomy, as it lessened the chance of sepsis of the peritoneum. The result in the two cases mentioned was perfect. In many of the cases a multiple synovitis was noticed.

Mr. FREDERICK TREVES (London) considered that many of these cases of non-malignant stricture of the rectum were really congenital in origin. The ordinary treatment was very unsatisfactory and he thought that Mr. Wallis's method was a distinct advance.

Mr. STANLEY BOYD agreed that some of these strictures were congenital in origin. One explanation of the frequency of non-malignant stricture in women was that the bowel was affected by discharges from the vagina.

Mr. R. J. GODLEE (London) asked Mr. Wallis if he had mentioned pelvic peritonitis as a cause. He suggested the ventral position as better for the operative treatment of these cases than the lithotomy position.

Mr. WALLIS, in reply, acknowledged that he had omitted pelvic peritonitis as a cause, but he had intended to confine his paper to strictures following on ulceration.

Oöphorectomy in Cancer of the Breast.

Mr. STANLEY BOYD (London) described the suggestion of this operation in 1896 by Beatson who relied on a theoretical analogy between the rapid multiplication of the gland-cells in lactation and in malignant disease. Whatever the value of the theory Mr. Boyd showed the striking result of the operation in certain cases. He provided a table detailing all the cases recorded up to date. These were divided into two classes; in the first were put those cases in which the beneficial effect of the oöphorectomy seemed clear and considerable; this contained 17 cases. In the other class were put the cases in which little or no effect was produced or in which the result was doubtful; these were 21 in number. In many of the cases thyroid extract was administered, but it was very doubtful if this had any beneficial effect. The best results seemed to be attained when the patient was over 40 years of age but before the occurrence of the menopause. The more slowly-growing cases were the most likely to be benefited. In some cases improvement occurred within a week. It was desirable in all cases to treat the growth directly by excision, reserving the oöphorectomy for recurrences.

Dr. G. E. HERMAN (London) completed the notes of two cases operated on by him which were included in the series of cases collected by Mr. Boyd.

The late hour precluded any discussion on this important paper.

OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, AUGUST 1ST.

Cephalotripsy of the After-coming Head.

Mr. J. H. TARGETT (London) read a paper on this subject founded on a case in which this plan was adopted. He premised that the operation was hardly referred to in ordinary text-books on midwifery and that therefore no details of the procedure were available. The occasions on which such an operation might be required were of course very rare, and even in the case which formed the subject of the paper he thought there was no doubt that Cæsarean section would have been the better method of treatment. The case was that of a rickety dwarf, aged 29 years, unmarried. She was near the end of the ninth month, and as she declined to have Cæsarean section performed it was decided to induce labour at once. This was done by hydrostatic bags, after which a leg was brought down. Delay then took place, and after some hours it was decided to extract. The trunk was delivered but the head remained in a position of flexion above the contracted brim. As no impression could be made upon it, and as pulsation in the cord had ceased, craniotomy was performed. The suboccipital region was chosen as being the most accessible. On applying the cephalotribe the lower blade came into apposition with the face of the child, but the upper blade could not be passed over the occiput owing to lateral contraction of the pelvis and incomplete dilatation of the lower segment of the uterus. The result was that the end of the blade repeatedly caught in the edge of the suboccipital perforation. This led Mr. Targett to pass the blade into the skull through this aperture and thus crush the base in its antero-posterior diameter. The plan answered admirably. The patient made a good recovery. The points on which Mr. Targett laid stress were: (1) What is the best site for perforation of the after-coming head? and (2) when crushing is necessary how should the cephalotribe be applied? He also raised the question of the supposed advantages of version before craniotomy. As to the first point he recommended the suboccipital region. The application of the cephalotribe was, he thought, best effected in the way which he had described in his case, because subsequent experiments which he had made had shown him that the best grip was obtained by inserting one blade into a suboccipital perforation, while the opposite blade was applied over the face. Dr. A. Donald of Manchester had recommended some years ago that version should be performed before doing craniotomy, and he (Mr. Targett) could testify to the fact that under these circumstances the delivery of the after-coming head presented no difficulties. The converse line of practice—viz., version after cephalotripsy—was, he imagined, very rarely adopted; but he had had occasion to carry it out in a recent case. Internal version in this case presented no special difficulties, but there was some trouble in bringing down the breech. After this, however, the rest of the delivery was surprisingly easy because the arms were completely extended by the side of the crushed head, and the mass so formed was less in bulk than the breach or the thorax. The patient did well.

The PRESIDENT (Dr. W. S. A. GRIFFITH) said that in the case of a dead child craniotomy was, in his opinion, preferable to forceps extraction in cases of contracted pelvis. But he had had such good results from Cæsarean section that in the case of living children he would be very loth to advise craniotomy.

Dr. C. E. PURSLOW (Birmingham) had in one case delivered by version when attempts to extract after perforation had failed, and he agreed with Dr. Griffith that this plan had advantages in some cases. When he had to perform craniotomy on the after-coming head he preferred perforation through the mouth to that behind the ear.

Mr. TARGETT replied.

Mdlle. CATHARINE VAN TUSSENBROEK (Amsterdam) read a short paper on Observations on Human Placentation in its Second Stage, illustrated by diagrams.

Dr. M. BEVERLEY (Norwich) and Dr. BERRY HART (Edinburgh) made some observations on the subject and congratulated Mdlle. van Tussenbroek on her excellent paper.

STATE MEDICINE.

WEDNESDAY, AUGUST 1ST.

Dr. DREW HARRIS (St. Helens) read a paper on

The Municipal Sterilisation of Milk: An Account of the Installation and Working of the System at St. Helens.

This paper was illustrated by lantern slides. The system was described in detail and results were given showing some improvement in the mortality of the children thus fed. The cost of sterilising the day's supply of milk was twopence, and the cost of installation and current expenses came to about £500, less £187 derived from the sale of the milk.

Dr. Harris's paper was discussed by Dr. J. C. THRESH (Chelmsford) and Dr. H. PECK (Chesterfield). The latter held that the proper way to begin the crusade was by a rigorous public control of the dairy farms.

Professor R. W. BOYCE (Liverpool) being absent, Dr. GRÜNBAUM read for him a paper upon the Construction of Sanatoria for Phthisis. Several continental institutions were described and illustrated by lantern slides, as was one in course of construction near Liverpool.

Dr. A. C. HOUSTON (London) read a paper bearing the title—

Can Modern Systems of Sewage Treatment be Depended upon to Remove the Bacillus Typhosus and Allied Organisms?

He showed a large number of lantern slides in illustration of his paper and confined his remarks to bacterial filters, because septic tanks in his judgment were no better from the epidemiological point of view than modified cesspools. In discussing the question of the possibility of the mechanical separation of micro-organisms in bacterial beds Dr. Houston gave good grounds for accepting his final conclusion—namely, that having regard to permanency of action and to what was feasible in practice it might be stated in general terms and with comparative safety that the mechanical separation of the micro-organisms in sewage by the use of bacterial beds was virtually impossible. In considering the possibility of the biological processes at work in the filter-beds proving inimical to pathogenic germs Dr. Houston pointed out that it was difficult, if not almost impossible, to obtain direct evidence on this important point because the mathematical chances of isolating the typhoid bacillus from ordinary sewage were so remote as to be almost infinitesimal. Consequently it was necessary to seek for indirect evidence, such as might, for example, be afforded by the enumeration of certain species of microbes in the crude sewage, and then to ascertain the fate of these same germs during the biological treatment of the sewage. Dr. Houston next gave elaborate tables proving that in the Crossness experiments bacillus coli and bacillus enteritidis sporogenes passed through the bacterial beds in practically undiminished numbers. Another microbe passing through the beds in unaltered numbers was the "sewage proteus," some strains of which were virulent to guinea-pigs. Again on occasion Dr. Houston had found bacillus pyocaneus even in so minute a quantity as $\frac{1}{1000}$ cubic centimetre of an effluent. Lastly, the subcutaneous injection of from 1 to 3 cubic centimetres of sewage effluents into guinea-pigs almost invariably produced a rapidly fatal result, but sometimes the animals apparently recovered but eventually died after the lapse of some weeks from pseudo-tuberculosis. Speaking of the deposit accumulating on the material in bacterial beds Dr. Houston showed that besides the tetanus bacillus "acid fast" bacteria were present in abundance some of which could not with certainty be distinguished morphologically from the tubercle bacillus. In one single instance he succeeded in producing tuberculosis in a guinea-pig inoculated with the deposit from a bacterial bed. Dr. Houston inferred from this that even if some of the "acid fast" bacteria collecting in the coke-beds were those of the tubercle bacillus they had for the most part lost their infective power; nevertheless, the single positive experiment recorded tended to destroy the belief that none of the bacteria in question were those of tubercle or that being tubercle they had all lost their infective power. Dr. Houston next dealt at some length with the experiments of Andrewes and Laws on the vitality of bacillus typhosus in sewage and with Klein's researches in a similar direction. The lesson Dr. Houston sought to teach from the results of these experiments was that the element of "time" or "delay" was an all-important factor and that it was doubtful if any bacterial process in practical operation at the present time "treated" or "detained" the sewage for a sufficiently long period to allow of the complete destruction of all the pathogenic germs by bacterial agencies. Dr. Houston frankly admitted that demonstration of bacillus enteritidis sporogenes and bacillus coli in sewage effluents did not of necessity prove that the typhoid bacillus and Koch's vibrio would likewise be unaffected by the biological processes at work in bacterial beds, but he urged somewhat strongly that his results showed that until positive evidence to the contrary were forthcoming it would be wise to regard the effluents from bacterial beds as no more safe in their possible relation to disease than crude sewage. In conclusion, Dr. Houston pointed out that if streptococci, as a class, were to be thought of as derived from the intestinal evacuations of animals as delicate germs which readily lost their vitality and died, and as not unlikely to be, moreover, pathogenic, the fact that he had repeatedly isolated them from $\frac{1}{1000}$ cubic centimetre or less of the effluents from bacterial beds could not be regarded as devoid of significance. Indeed, in Dr. Houston's judgment it clearly carried the conviction that if these germs of feeble vitality passed through the filters in practically unaltered numbers it was extremely unlikely that pathogenic germs such as bacillus typhosus and the cholera vibrio which were seemingly most resistant, would be destroyed altogether during the biological processes at work in the filter beds.

Dr. A. S. F. GRÜNBAUM (Liverpool) said that the bacillus enteritidis sporogenes was almost universal. He did not think that the bacillus coli was very resistant, for it was specially susceptible to light and dryness. The great difficulty at present lay in the fact that there were no means of isolating the bacillus typhosus. Recently a cultivation medium had been published by Dr. A. T. MacConkey in THE LANCET[1]—a bile-salt agar with lactose which was inimical to nearly all bacteria but bacillus coli and bacillus typhosus. They had found that the bacillus typhosus was not present in the effluent from three feet of sand. The result of these observations pointed to the conclusion that all typhoid excreta should be sterilised. Effluents from bacterial beds must not go anywhere where they would be likely to infect drinking-water, or food, such as oysters.

Dr. COOPER PATTIN (Norwich) had endeavoured for a long time in Norwich to get excreta mixed with paraffin and burnt. As Dr. Grünbaum pointed out, the infection could not be kept out of the sewers either in early or in ambulatory enteric fever cases. Filter-beds did not clear sewage of pathogenic bacteria. He asked Dr. Houston to what extent and for what period of time must sewage be passed through soil to rid it of infection. It was a question whether the bacilli should not be subjected to treatment before filtration.

Dr. J. GROVES (Carisbrooke) said that the Local Government Board had discouraged the efforts of small authorities to establish bacterial treatment of sewage. The microbic states of effluents were most unsatisfactory. Many medical officers had been convinced that there had been an actual increase in the bacteria of the effluent from filtration beds.

Dr. J. C. THRESH (Chelmsford) said that at Whitstable, where oysters were cultivated, the question arose whether it would be safe to discharge effluents. On experimenting he found more bacteria in the effluent than in original sewage. The Local Government Board had pressed them to enlarge their filter-beds. He urged his local committee to write asking for proof that bacillus typhosus and other pathogenic germs would thereby be eliminated. The Local Government Board admitted that there was no such proof. The danger was the greater inasmuch as the effluent contained nothing offensive to the eye or the nose.

Dr. HOUSTON, in reply, said that he was pleased to find that Dr. Grünbaum did not regard the bacillus coli as a resistant organism. The general view was that the bacillus coli was more resistant than the bacillus typhosus. The new medium of Dr. MacConkey was doubtless most important. The use

[1] THE LANCET, July 7th, 1900, p. 20.

of sand as a material for efficient filtration could not be carried out in practice. Dr. Pattin's question as to what was the most efficient method of sewage sterilisation was difficult to answer. It might be said, however, that subsequent earth filtration would greatly lessen, if not remove, the infection.

THURSDAY, AUGUST 2ND.

The Provision of Cottages in Rural Districts and its Bearing upon Public Health.

A discussion was opened upon this subject by Dr. J. S. TEW, medical officer of health of the West Kent Combined Sanitary District. This subject, he said, was inseparably connected with the larger question of the housing of the working-classes throughout the country and was of paramount importance. He did not think he was claiming too much in saying that to no one was the actual condition of life among the working-classes better known than to members of their own profession and particularly to those of them who had been engaged in general practice and who had therefore seen all phases of cottagers' lives. The President of that Association last year, in his comprehensive and able address, spoke as follows: "The great hindrance to the progress of preventive medicine which we have to overcome is the overcrowded and insanitary condition of the dwellings of the working-classes. This is the field on which the great battle will have to be fought out. Our warfare will not be directly with microbic life, but rather with the conditions in which specific organisms are grown." In considering the condition and requirements of so-called rural districts, it had always appeared to him that some explanation of the term should be made. The term "rural district" might be considered, as far as the question of housing was concerned, in two ways: (1) when viewed in the light of the legal powers of its governing authority as a *rural* district—i.e., as an arbitrary division, distinguishing it from *urban* districts; and (2) when viewed as to its actual constitution—i.e., in the light of its proportion of population to area and the occupation of its inhabitants. Many large "rural districts," particularly in and near manufacturing and mining parts of the country and in districts near London and large towns, included contributory places of an urban character, and were rural only in name, and it was important to recognise their difference from purely agricultural districts. It was only reasonable that where houses for the working-classes were inadequate the consideration of building by local authorities and the nature of the dwellings most suitable to meet the local wants must be regulated by the constitution of the district and by its prevailing industries. For that purpose he proposed some such division as the following: (1) the metropolis proper, the condition of which was unique and with the exception of certain generalities beyond the scope of that discussion; (2) suburban districts, where the question of accommodation was somewhat less acute than in the actual centre of London; (3) extra-suburban districts—i.e., just beyond the immediate suburbs, often some 15 or 20 miles out, and many of which were in a transition state, but gradually losing their rural character by absorption into the suburbs of the spreading metropolis; (4) agricultural districts, where the poorer classes mainly, if not entirely, worked on the land; (5) cities and large provincial towns, where in the majority of cases special conditions of situation, staple industry, &c., made the question of the necessity for further provision of houses for the working-classes almost purely local; and (6) the suburbs of cities and large provincial towns, respecting which the conditions were extremely variable and must be dealt with on their individual merits. The districts coming under the head of rural districts would mainly be under the divisions Nos. 3, 4, and 6, and the working-people resolved themselves into three classes: 1. A section in good work and receiving wages varying from 25*s.* to 30*s.* a week, but yet where there was the greatest difficulty in obtaining a decent dwelling for a family, from 6*s.* 6*d.* to 8*s.* 6*d.* being frequently paid as house-rent alone in districts indicated as "extra-suburban." This led to the inevitable lodgers and the consequent overcrowding with the attendant evils. 2. A section mainly including the ordinary agricultural labourer, with a varying wage of about from 12*s.* to 22*s.* a week. In many cases, particularly on large estates, this class was well housed in cottages from 1*s.* to 2*s.* 6*d.* a week rent with a good garden and often a supply of milk; in others the cottages might be cheap, under 2*s.* a week, but too small for a family, damp, ill-drained, badly supplied with water, and in a bad state of repair. Many of these cottages were let with farms and the tenant farmer was the employer and sublet the cottages to the labourers. In this case if the cottage was in bad repair it was difficult or impossible for the labourer to get his master to insist on repairs, as the farmer was reluctant to request the landlord or his agent to improve the condition of the labourer's cottage, having in these days of agricultural depression many other and, in his opinion, more pressing matters on which to obtain his landlord's consideration. As a rule, however, the worst class of cottage was that owned by poor persons who had to live out of the proceeds of old cottage property, frequently mortgaged, and where practically no repairs had been done for years, and interference meant the owners becoming chargeable to the parish. Cottages owned by labourers themselves were rarely in satisfactory condition. 3. The third and, fortunately, by far the smallest section in rural districts would include those having no regular occupation and having an alternating existence between a slum cottage, the workhouse, the gaol, and the road. That was the class which so frequently came under the notice of the Society for the Prevention of Cruelty to Children and the school attendance officer and the children of whom were such active agents in the spread of infectious and parasitic diseases in our elementary schools. The bad influence which insanitary and overcrowded cottages had upon the public health could hardly be over-estimated. To his mind the foremost evil was the lowering of the individual stamina of those living under bad conditions. Next to this came those two most formidable diseases of infant life, whooping-cough and measles, which between them in the year 1899 caused in England and Wales over 19,000 deaths, the vast majority of these occurring among children of the working-classes. The obstacles to the provision of an adequate number of healthy cottages in rural districts were many and great, so great that although increased powers to provide accommodation were given ten years ago yet he believed that so far only two rural district councils in England had reached the stage of actual buildings. Proposals to adopt Part III. of the Housing of the Working Classes Act had, however, in many instances stimulated local enterprise to provide the necessary accommodation. Unfortunately, in the majority of rural districts the staff of sanitary inspectors was inadequate and only sufficient to cope with routine work and general nuisances, leaving little time for the detailed inspection of cottage property, which frequently belonged to persons with local interest who had the power to oppose the annual re-election of inspectors. With insecurity of tenure it was unlikely and unreasonable to expect that the majority of sanitary inspectors or medical officers of health would take the active steps which they otherwise would. Again, the clerks to rural authorities naturally had no great enthusiasm in the matter of adopting acts of this kind which required great attention and caused endless extra meetings, and as experience showed in the great majority of cases eventually were allowed to fall through at any earlier or later stage. When it had been fairly shown that further cottage accommodation was required fresh housing should be made before closing of insanitary property, otherwise the ejected families either overcrowded other cottages near or else left the neighbourhood. The all-important question in starting a scheme was whether the cottages would be self-supporting or become a burden on the rates. Where land was not high-priced he had every reason to believe that with care and economy, even with the present high price of material and wages, rural councils could build cottages just to pay their way; and if from exceptional local circumstances there was a slight loss on them it should be looked upon in the light of an insurance premium on the health of the place. They naturally looked with considerable expectation to the Bill now before Parliament to amend Part III. of the Housing of the Working Classes Act, 1890, but a perusal of the Bill as amended in committee gave little hope of making the mode of procedure less cumbersome for rural districts. He hoped to elicit opinions specially (1) as to the urgent necessity for better cottage accommodation in many rural districts; (2) as to the desirability of rural district councils undertaking the building of cottages; and (3) as to the insufficient air-space in crowded cottages being greatly responsible for the high death-rate among the working-classes from such diseases as measles, whooping-cough, and phthisis.

Dr. J. GROVES (Carisbrooke) said that the inspectors had

to collect information for the medical officers. In many rural districts landlords had to be dealt with directly. The landlords had often very little return and it must therefore be shown clearly that better accommodation was necessary. Cottages were often closed by the local authorities because landlords would not repair them, and the labourers were forced into the nearest towns. The duty of the medical officer was to state what was right from a sanitary point of view, but the responsibility of carrying out his recommendations rested with the local authority. Security of tenure was the only safeguard and that could be obtained only by the Local Government Board.

Dr. H. PECK (Chesterfield) related a number of instances of country persons in his district who lived in extremely bad houses. The present system of providing houses under the Housing of the Working Classes Act was far too complicated. Until that was simplified there was little chance of making any material improvement in rural housing.

Sir HUGH BEEVOR (London) said that the question should be mainly in the hands of the county medical officers. He suggested that the dampness of cottages might be ascertained in country districts and valuable data thereby afforded in the study of phthisis.

Dr. D. G. SUTHERLAND (Cambridge) suggested that rural improvement schemes might be run alongside the many that were advanced in favour of towns. The hands of the sanitarian were often stayed because he knew that if insanitary houses were condemned no others would be built in their place. The stamina of the nation was deeply involved in the question of the housing of the rural poor.

Dr. J. HADDON (Hawick) thought that medical officers of health did not fully avail themselves of existing powers. He urged that powers should be given to regulate the construction of cottages and that an isolation room should be attached to each dwelling.

Dr. H. JONES (Rhondda) lamented the insufficiency of the staff and the apathy of the Local Government Board in the matter. At the same time pressure from that body, however, was often ignored by the local authorities.

Dr. TEW, in reply, said that insecurity of tenure retarded both inspectors and medical officers. He agreed with Dr. Peck that the trouble given to the clerks by Part III. of the Housing of the Working Classes Act was most detrimental. There was no more striking feature in country cottages than the gutters, which were very often very defective and led to damp walls.

A vote of thanks to Dr. Tew was proposed by the PRESIDENT and carried unanimously.

PSYCHOLOGY.

WEDNESDAY, AUGUST 1ST.

The Bearing of Sexual Functions and Diseases of the Sexual Organs on Insanity and Crime.

Dr. MACNAUGHTON-JONES (London) opened a discussion on the Correlation between Sexual Functions and Insanity and Crime. He pointed out that various affections of the genitalia, internal and external, might have possible correlative mental disturbances and that malpositions and displacements of the uterus and adnexa, inflammatory and neoplastic lesions, and perverted sexual habits—e.g., masturbation—might give their characteristic colour to mental troubles. Insanity might arise from masturbation as well as from the changes attending the onset of sexual life (puberty and adolescence) or its close (the menopause). Psycho-pathology and gynæcology had a common meeting-ground in the sexual ailments of women, and in this field might be found the causes and conditions which in women gave rise to neurasthenia, hypochondriasis, melancholia, mania, and dementia. Hystero-psychoses had their origin in uterine and ovarian troubles, as was now almost universally recognised. Much depended upon difference of environment and upbringing. The sensitiveness of the cultured, refined, and pretty woman of society might result in mental trouble from causes which did not affect the agricultural labourer's wife, the city seamstress, or the factory hand. Special regard should be had to the importance of the period of adolescence from a medico-legal and criminological standpoint. The question of the gynæcological examination of female patients who were insane must be left to the discretion of the asylum physician. When gross lesions or tumours of the uterus and adnexa were present in such patients removal should be practised. The risk of post-operative mental derangement was slight or absent in women previously healthy, and when such derangement resulted it was not generally serious or permanent. Aberrant uterine and sexual functions when present in a woman who had committed some crime or offence should be always carefully considered because such a condition might be a determining cause, and its removal might do away with the tendency to crime or wrong-doing.

Dr. J. G. SOUTAR (Gloucester) deprecated undue gynæcological examination of female patients, especially as a routine practice, this being decidedly a disturbing process.

Dr. BERNARD O'CONNOR (London) said that the approach of the menopause should be considered as an important point in determining the criminal responsibility of women at the age of 43 or 44 years.

Dr. WYNN WESTCOTT (London) said that in his experience as a coroner at inquests on 200 women who had committed suicide he found that the majority were at the "change of life" and that the younger of these appeared to have been menstruating.

The PRESIDENT (Dr. PERCY SMITH of London) deprecated the routine vaginal examination of female lunatics and stated that some gynæcological methods tended to develop the patient's hypochrondriasis.

Dr. SEYMOUR TUKE (London) commended the coöperation of psychological and gynæcological study.

Mr. G. A. CARDEW (Cheltenham) said that gynæcological examination was unnecessary in the vast majority of cases seen by him—i.e., female school teachers and students, who suffered from amenorrhœa, but who recovered under rest, fresh air, and good diet.

Dr. MACNAUGHTON JONES briefly replied.

Epileptoid Mania.

Dr. E. S. PASSMORE, assistant medical officer of Banstead Asylum, read a paper on Epileptoid Mania. Patients suffered for some years from fits, probably from childhood, and then some day, without warning, mental symptoms of a characteristic kind supervened on a fit. The mental symptoms were confusion of ideas and loss of memory and the unconscious performance of some apparently purposive act. At a later stage maniacal outbreaks of an impulsive or homicidal character might develop, and temporary delusions might also arise as the result of hallucinations. In other cases the convulsive attacks were entirely absent, their place being taken by periodical maniacal outbursts. Clinical histories of a few cases were detailed and the conclusion reached was that the periodical convulsive attacks of epilepsy might in some patients be replaced by periodical maniacal attacks (psycho-epileptic attacks). It was also urged that so called "recurrent mania" was nothing but an epileptic insanity. For example, a female patient, aged 31 years, admitted to Banstead Asylum as suffering from acute mania in 1884, was discharged in 1887. Eight days later she was readmitted with acute maniacal symptoms. After four years she was discharged, but readmitted in five days, and had since then been a constant inmate of the asylum. Her attacks of maniacal excitement now occurred at shorter intervals than previously and between the attacks she was perfectly rational. The attacks had a comparatively sudden onset, with twitching of the facial muscles and mental confusion lasting a few hours. She then became maniacal and dangerous and exhibited murderous impulses. When this stage had subsided she was dirty and destructive in her habits and collected rubbish. The whole attack lasted a week or a fortnight and she then slowly recovered. After an interval the same cycle of events was repeated. The patient's brother and sister were insane, but no other details of family history were obtainable. In other patients similarly afflicted a family history of insanity and epilepsy was obtained. Dr. Passmore concluded that the mania associated with ordinary epileptic insanity and that known as recurrent mania showed a marked similarity in clinical symptoms, and he suggested that such cases of recurrent mania as exhibited periodical excitement in the absence of delusions should be regarded as epileptic in nature and should be designated "epileptoid mania." Of course such conditions as general paralysis, chronic alcoholism, and cerebral wasting, in which epilepsy was merely symptomatic, should not be confounded with these cases.

Mr. F. OLDFIELD (London), in discussing the above paper, said that epilepsy might be manifested by mental symptoms, especially such mental outbreaks as certain criminals were liable to and which Lombroso was one of the first to draw attention to.

Dr. LLOYD ANDRIEZEN (London) referred to the importance of classification as a scientific, practical, and economic measure, and to the places and institutions adapted for various classes of epileptic patients. Epileptic lesions might be present in idiots, imbeciles, paraphreniacs (criminals, borderland cases, &c.), and in ordinary lunatics. Psychic epilepsy led to the development of automatic states of sub-consciousness, with loss of the sense of personal identity, during which crimes might be committed. This was a point of great medico-legal importance. He could not accept the view that true recurrent mania was identical with epileptic mania. Both in pathogenesis and clinical history there were important differences.

The PRESIDENT did not consider recurrent mania as an epileptic cerebral or mental disease. Attacks of recurrent mania usually began more gradually and there were less confusion of mind and loss of memory for the occurrences than in epileptic insanity. There was some relationship to epilepsy in rare instances—e.g., in a case observed by him in which one of the maniacal attacks of a patient suffering from recurrent mania ended with a series of convulsive seizures.

Dr. J. G. SOUTAR said that in many essential particulars recurrent mania proper was different from epileptic insanity, and Dr. Passmore's contention of their identity could not be sustained. It was necessary to guard against a too great laxity towards criminals by ascribing criminal deeds to epilepsy.

The meeting was then adjourned to the next day.

PHYSIOLOGY.

WEDNESDAY, AUGUST 1ST.

The proceedings of the section opened with a debate on

The Formation and Excretion of Uric Acid in Health and Disease,

introduced by the President, Dr. W. D. HALLIBURTON, Professor of Physiology in King's College, London. He said that their more exact information on the subject dated from the work of Mares and Horbaczewski, the former of whom pointed out that the increased output of uric acid following a meal commenced too soon to be attributable to tissue metabolism, and the latter associated the production of uric acid with the liberation of nuclein. Horbaczewski's theory, though not tenable in all its original details, had been the basis of most of the more recent work. Chemists as well as physiologists had given attention to the matter, and one in particular, Fischer, had done good service in showing the possession by uric acid and the alloxuric bases of a common radicle—purine. Smith Jerome found that feeding on foods containing nuclein always increased the output of uric acid in the urine, whilst Hopkins and Hope pointed out that the insolubility of nucleins in gastric juice precluded the assumption that they furnished the whole of the uric acid immediately following a proteid meal, and further, that the quantity of uric acid produced by a *flesh* diet was too great to be wholly due to the small amount of nuclein therein contained. But flesh, though poor in nuclein, was rich in purine bases (particularly in hypoxanthine), and this, according to Smith Jerome, accounted for much of the uric acid in the urine. The uric acid of the urine was not the whole of the uric acid produced in the body. According to Kossel and Goto uric acid formed combinations with nucleic acid, at all events, *in vitro*; such might also be the case *in vivo*. Hugo Wiener found that a "surviving" liver could destroy uric acid, as could also extracts of other organs, and Parker described excretion of purine-containing substances into the bowel. Burian and Schur stated that every healthy adult excreted in urine a fairly constant quantity of purine bases characteristic of himself and apart from his food (endogenous urinary purine); and in addition, through the same channel, purine derived directly from his food (exogenous urinary purine) in quantity characteristic of the foodstuffs and not of himself. Further work on these lines promised well for the elucidation of purine problems in general and of the particular purine problem now before them—viz., that of uric acid.

Dr. A. HAIG (London) had examined his urine on nearly 3000 days and had come to the conclusion that the amounts of uric acid and urea formed in the body bore a constant ratio to one another—viz., 1 to 35. Excretion was more variable than was formation of uric acid, owing to control over the amount of uric acid ingested and over its solubility. In this country disease due to uric acid was caused rather by its ingestion than by its formation in the body.

Dr. T. H. MILROY (Edinburgh) referred to the importance of metabolism as a factor in the production of uric acid. Uric acid could certainly be produced from nucleins in food, but equally certainly from the nucleins of living cells. Nuclein-metabolism in birds was analogous to that in mammals. Dr. Milroy would speak further on the metabolic side of the question at a later meeting of the section.

Dr. F. G. HOPKINS (Cambridge) emphasised the origin of uric acid from non-nuclear sources. Administration of fruits might greatly reduce the output of uric acid and this probably rather by preventing its synthesis than by hindering its separation when formed.

Dr. W. J. SMITH JEROME (Oxford) considered it to be proven that some of the uric acid excreted was not derived directly from food, and that as much of it as did come from food was derived from alloxuric nitrogen. He commented on the supposititious nature of many statements made on the subject.

Dr. J. HADDON (Denholm) referred many disorders of nutrition to excess of food, more particularly to that of animal origin.

Dr. HARRY CAMPBELL (London) observed that attacks of gout and gravel were rarely synchronous. The quantity of food taken was as important a factor as was its quality in relation to uric acid production.

Dr. R. J. ANDERSON (Galway) considered that the nervous system was responsible for many variations in tissue activity and in activity of excretory organs.

Dilatation of the Pupil from Cortical Stimulation.

A paper was read by Dr. J. HERBERT PARSONS (London) on the above subject. Experiments on dogs and cats, he said, showed that dilatation of the pupil was not necessarily associated with deviation of the eyes or other movements. It was best obtained by excitation of the "oculomotor" and "visual" areas of the cortex and was abolished by excessive anæsthetisation. When well marked the pupillary effect was accompanied by all the usual results of stimulation of the cervical sympathetic and was usually more pronounced in the contra-lateral eye. The effect was diminished but not abolished by section of both cervical sympathetics; it was, on the other hand, completely abolished by intracranial division of the oculo-motor nerves subsequently to cutting the sympathetics. Division of the corpus callosum did not prevent the effect. Excitation of the central end of a cut afferent nerve still caused dilatation after cutting the sympathetics. This must be due to inhibition of the third nerves.

Dr. E. W. CARLIER, Professor of Physiology in the University of Birmingham, read a paper on

Changes in the Cell of the Newt's Stomach during and after Secretion.

Much of the work done on this subject was communicated to the Association at Edinburgh and the present paper was an appendix thereto. As the cell parted with its zymogen a new substance—prozymogen—was produced by the nucleus at the expense of the chromatin. This prozymogen became zymogen, which was not discharged until the nuclear chromatin was again restored. During secretion the nucleoli increased in size, were discharged into the cytoplasm, and disappeared, new ones immediately replacing them. They were probably excreta. The paper was illustrated by microscopic preparations, lantern slides, and diagrams.—Dr. R. J. ANDERSON and Dr. T. H. MILROY took part in the ensuing discussion.

Professor CARLIER also demonstrated Microscopic Preparations of the Kidney showing Cilia-like Projections from Cells lining the Convoluted Tubules. These had not previously been shown in the case of man. Analogous cells were obviously motile in amphibia but no ciliary motion had ever been seen in them in mammals.

Dr. A. G. LEVY (London) read a paper on

Fatigue of the Cerebral Cortex.

The motor cortex of the cat was excited by faradaic currents and contraction of the correlated muscle recorded. This did not fatigue the muscle itself. With sustained excitation the muscular contraction was at first tonic but became clonic as fatigue supervened. The onset of fatigue was rapid, contraction of the muscle rarely lasting for more than 30 seconds. Rest restored excitability. Cortical fatigue could also be elicited by repeated short excitations at regular

intervals. Under these circumstances irregularity of response preceded failure to react. The paper was illustrated by reproductions of tracings.

Dr. D. F. HARRIS, Lecturer on Physiology in the University of St. Andrews, read a paper on

The Inertia of Protoplasm.

Analogy might be drawn between the inertia of inanimate matter and certain properties of protoplasm. Thus one might conveniently speak of anabolic inertia of protoplasm (i.e., its resistance to excitation) and of katobolic inertia (i.e., its tendency to continue active after cessation of a stimulus). The former state was instanced by all "latent periods," the latter by the continued activity of isolated tissues. The terms also lend themselves to description of psychical states—e.g., apathy and superstition on the one hand and habit and fanaticism on the other.

OPHTHALMOLOGY.

WEDNESDAY, AUGUST 1ST.

Presidential Address.

Dr. W. A. BRAILEY, ophthalmic surgeon to Guy's Hospital, took as the subject of his address Ocular Headaches—that is, headaches in association with refractive and muscular errors. While the great majority of headaches were, he said, independent of the eyes, it was a matter of general acceptance that ocular errors produced headaches, though by no means in all cases. Were there any errors especially effective in the causation of headaches or in producing any particular form of headache? Muscular errors were by far the most important, though, of course, these must be ultimately of nervous origin. Other influences than muscles were glare and sudden irregularities in the distribution of light, such as flickering. Muscular ocular movements were intrinsic (pupillary and accommodative) and extrinsic (of the recti and obliqui muscles). The pupillary movements were unimportant except as slightly influencing glare. The accommodative movements were bound up with the great majority of ocular headaches.

It was a general law that the larger the ocular error the less the effect produced on the head, the reason being that a great defect of accommodative power led to its abandonment, the patient seeing as best he could without it. So also uncorrected presbyopia was rare as a cause of headache, except just at its commencement. It might cause strain and burning but not headache. A highly hypermetropic patient would read close with poor vision but no aching. So also patients with high hypermetropic astigmatism. Similarly great inequality of refraction gave comparatively little trouble, the worse eye being abandoned to disuse and muscular action being regulated by the better one. High degrees of myopia and myopic astigmatism produced little effect, distant objects hardly being seen, while near vision could be remedied largely by adjusting the distance. But low degrees of hypermetropia and hypermetropic astigmatism were often causes, especially when they led to an excess of effort both in amount and duration beyond that which was needed, as with weak muscles or hyper-sensitive nervous supply, this spasm of accommodation continuing in distant vision, and even under retinoscopy in the dark. But both spasm and headache were more produced by moderate inequality of refraction, especially if astigmatic and most of all by astigmatism with asymmetry of the axes. The ciliary muscle appeared to act unequally on the two sides in correcting this or a muscle even in different parts of its circuit in remedying astigmatism or asymmetry of axes. Evidence of this was seen when atropine revealed astigmatism on one side or both, increased its amount, or altered the axis of the correcting lens in amount less than 90°. So astigmatism, often unequal-sided, might become manifest when presbyopia began, and refractive defects revealed themselves to retinoscopic examination in eyes blind with fundus changes, such as optic atrophy, in proportion beyond that observed in average-seeing eyes. The above refractive errors caused aching in the eyes, often passing presently or on the following morning into the brows, immediate aching in the brows, temples, the back of the head, and occasionally also headache of the type of migraine. Treatment by appropriate glasses was of extreme value. Errors of the extrinsic muscles produced headache, but less than of the accommodative muscles, though more migraine, more giddiness, and more general distress. Here, also, the rule held that the larger the amount of error the less the disturbance, the explanation being that in considerable degrees of strabismus the image fell on the peripheral and so less acutely seeing retina.

But another potent factor in headaches was the tendency to binocular vision, and so we had another rule—the stronger the tendency to binocular vision the more headache produced by an error of the recti and obliqui muscles. Binocular vision varied much in its strength in different subjects. Possibly there were natural differences related to the centres as much as to the muscles, for he had seen such indisposition run through families. But binocular vision appeared to be generally made rather than born. Babies often squinted irregularly till after a few weeks of life they got their yellow spots gradually to accord. He had met cases where, instead of bringing them into harmony, the child had developed another retinal point to work with the opposite yellow spot in an eye congenitally squinting, though with fair concomitant movement. Rectification of such apparent squint by tenotomy would produce diplopia. Other cases were common where the two eyes remained quite independent; for example, where there was congenital want of power of both external recti from central defect diplopia was absent and the child saw to his left with the right eye, and *vice versâ*. Binocular vision was not strongly established by the early age at which ordinary concomitant squint arose; so diplopia, though present, gave no trouble, and, indeed, was little noticed even in the comparatively rare cases where each eye had normal refraction and vision. But to take the case of a paralytic strabismus—for example, of the superior oblique—suddenly arising in an adult: here was much disturbance, and the same with cases where, when the two eyes had been used for different purposes—that is one for near and the other for far—they suddenly attempted by lenses and prisms to unite the images, the results being distress, giddiness, migraine, and other headache. But extrinsic muscles might, like the ciliary, have large latent defects, and he suspected that many obscure cases of headache had their solutions here.

Besides individual tendencies other influences altered the disturbing effect of ocular errors: (1) age, the errors being most potent between the ages of 10 and 45 years; (2) sex, women being the greatest sufferers; and (3) nationality. His experience did not extend much beyond the English people and the citizens of the United States, the latter of whom were eminently affected by these errors, so that a series of medical men and operators had arisen to take charge of that special sub-section of practice. Doubtless there were other influences, such as occupation and temporary states of the nervous system.

The Treatment of Chronic Glaucoma.

In opening a discussion on this subject Mr. RICHARDSON CROSS (Bristol) said that he based his opinion not only upon general experience but upon 47 private cases which had been most carefully examined and noted. Although all were agreed as to the necessity of operating on acute cases, yet many held different views as to the desirability of treating chronic cases in the same manner. The first and most important question was the diagnosis, and he considered that the field of vision was of the utmost importance, and observation on this gave the most valuable information in distinguishing between some cases of optic atrophy and chronic glaucoma, the contraction on the nasal side being very characteristic. If the disease had progressed very far probably nothing would save the eye, but in all other cases he was strongly in favour of iridectomy, and the sooner this was done the better. It was a comparatively simple thing to perform the operation in an early stage with a quiet eye, but very different with the reverse condition present. In some few cases where the tendency to the disease was very slight it might be kept quiet and non-progressive for years by the aid of myotics only, but usually the disease was not stayed by this alone. He mentioned an interesting case of myopia of 3 D with glaucoma where the myopia increased to 12 D, but the glaucoma got no worse. He then showed various charts of fields of vision both before and after treatment with myotics and iridectomy, and in most an increase of the field followed the diminution of tension. In one case considerable improvement followed iridectomy, but it subsequently deteriorated. He thought sclerotomy a most useful operation and proferred to do it with a keratome rather than with a Graefe's knife, and in the early stages he preferred this operation to iridectomy. He also considered that blindness would

follow in any well-marked case if drugs alone were relied upon.

Dr. J. HERN (Darlington) thought that the early diagnosis was the one thing needful and he considered that the relation between glaucoma and optic atrophy was very intimate. He was much in favour of establishing a communication between the anterior chamber and vitreous by passing a knife backwards (after iridectomy) through the cornea and suspensory ligament.

Mr. WORK DODD (London) said that his experience of iridectomy was not very satisfactory and he had been led in one case to excise the superior cervical ganglion of the sympathetic with immediate benefit.

Dr. KARL GROSSMANN (Liverpool) had seen much benefit arise from the sub-conjunctival injection of normal saline solution, and he sometimes increased the strength to 2 per cent.; this could be repeated every day for a week or longer.

Mr. E. D. BOWER (Gloucester) was in favour of prolonged treatment with eserine and cocaine. His experience of iridectomy was that in many cases the disease progressed.

Mr. GEORGE A. BERRY (Edinburgh) said that he used myotics for a long time only in the very early stage of chronic glaucoma, but this sometimes lasted for a very long time and he mentioned one case in which the sight was no worse 18 years after the disease was discovered. In all other cases he advised iridectomy and the sooner it was done the better. He preferred the keratome for both sclerotomy and iridectomy.

Mr. DEVEREUX MARSHALL (London) thought that the operation proposed by Dr. Hern was a very dangerous one and that injury to the lens and ciliary body would be very likely to occur.

The PRESIDENT thought that the disease was cured when the tension was normal, but atrophy of the optic nerve might progress and cause loss of vision. He favoured very early operation in nearly all cases.

Mr. RICHARDSON CROSS briefly replied.

Dr. KARL GROSSMANN demonstrated a lantern which he had invented for the detection of low degrees of colour-blindness.

Mr. SYDNEY STEPHENSON (London) read a paper on the Etiology of Phlyctenular Affections of the Eye. He noticed that in a very large number of cases there was either eczema or tuberculous tendency.

In the absence of Mr. G. FOGGIN his paper on Epicanthus was read by the SECRETARY, Mr. W. W. Sinclair. The author pointed out that the flatness of the nose was probably due to undue tightness of the cheek-muscles and tissues preventing the proper expansion of the nasal bones. He suggested a new method of raising the flat-nose bridge by means of subcutaneous division of tissues.

DISEASES OF CHILDREN.

WEDNESDAY, AUGUST 1ST.

Dr. NESTOR TIRARD (London) introduced the subject of

The Nature and Varieties of Pneumonia in Children

in a very lucid and interesting paper. Pneumonia, he said, in adults was a very satisfactory subject to lecture about on account of its well-marked character, physical signs, and symptoms, the chief variations from type being due to more or less involvement of the lung substance or to constitutional or acquired tendencies, such as alcoholism, of the patient. There were decidedly greater difficulties in dealing with pneumonia in children. Broncho-pneumonia seemed to have attracted more attention in children, hence some of the difficulty in diagnosis. The distinction was not well defined between broncho-pneumonia and vesicular bronchitis. Broncho-pneumonia was common in children up to the age of three years, after that age many cases conformed to the true lobar or croupous kind. The extent of the lung engorgement was greater in children than in adults, and this probably was responsible for the confusion with broncho-pneumonia. A general infection was evident in considering the symptoms and signs of acute pneumonia in children. This general infection had been attributed to the action of various micro-organisms, pneumococcus, &c., hence an anti-pneumonic serum had been used; but the subject had not yet reached a satisfactory stage. It was very doubtful whether pneumonia was really contagious. Dr. Pepper, the well-known American pharmacologist, had, indeed, given a series of instances, but generally contagious pneumonia had been pneumonia closely following influenza. The cases already in a ward did not produce more cases of pneumonia in those already there for other complaints. One case was quoted of a nurse who had nursed a patient suffering from diphtheria and who developed pneumonia and died. Speaking of abnormal forms of pneumonia Dr. Tirard said that the temperature might be abnormally high, say up to 106° F., either at the beginning or just before the crisis; there might be an unusually sharp crisis and a fall of 9, 10, or 11½ degrees; and there might be wide oscillations of temperature (5 degrees of difference—e.g., between the night and the morning temperatures) which was apt to confuse diagnosis. In one case the crisis occurred as usual at the fifth day; in a second the oscillations kept on for some weeks. This keeping up of the temperature might be due to other causes, such as an attack of diarrhœa or to extension of disease to other lobes of the lung. The initial symptoms were occasionally like those of tuberculous meningitis—headache, squint, retraction of the head, and vomiting, or the sickness and delirium might suggest cerebral tumour. As to abnormal physical signs, in spite of high temperature (of tableland character), rapid respiration, and all indications that the child had pneumonia, there might be no physical signs observable. In two cases quoted the physical signs (dulness and tubular breathing) only appeared at the crisis. Dr. Tirard gave a bad prognosis in the case of anæmic infants. He suggested that the cerebral symptoms and high fever were probably due to the retention of toxins in the blood in place of their being eliminated by the lungs. The difference in type might be due to different organisms, such, for instance, as the influenzal kind, which was not quite a true lobar pneumonia. He also touched upon the gradual development of tubercle out of an attack of presumed pneumonia.

Dr. LORIMER HART (London), after congratulating Dr. Tirard on his introduction to the discussion, dealt with the various forms of broncho-pneumonia, vesicular bronchitis, and pneumonia. His explanation of the nurse's case alluded to by Dr. Tirard was that it was a true diphtheria of the lung. He had seen six cases of pneumonia (in adults) in which the patients all died from heart failure; this he suggested was due to contagion, and in these cases possibly the anti-pneumonic serum might be of service. He believed that cases of pneumonia in children which presented cerebral symptoms were nearly always cases of special disease of the lung. Further, where the physical signs were late in appearing he suggested that the explanation lay in the disease gradually spreading from the interior of the lung to the surface. He considered that it was possible to arrest the progress of the complaint, engorgement of the lung in some cases not advancing.

Dr. H. O. NICHOLSON (Edinburgh) gave some valuable information on the question of pulse and blood-pressure in this disease. After the third day the pulse was dicrotic and the blood-pressure was low. In croupous pneumonia at the onset the pulse was hard and at high pressure, and after three days or so it was dicrotic and at low pressure. The tracing was irregular and the pulse was rapid. It was in some cases very like that gained from a tracing of mitral stenosis. In broncho-pneumonia there was not the same high tension at first nor quite the same tendency to fall. In unfavourable cases the high-tension pulse persisted. The chief indication of treatment suggested by study of the pulse was to sustain the blood-pressure. Digitalis did not seem so useful as strophanthus, strychnine, and carbonate of ammonia. In the first day or two of croupous pneumonia antimony was of much value.

Dr. A. M. GOSSAGE (London) dealt with the relationship of lobar and lobular pneumonia. Both might be due to the same pneumococcus. Clinically they were not much alike. Possibly the lobar pneumonia case got infected through the blood, the lobular through the lungs, and cases were met with where there was great difficulty in assigning them to one or the other. He explained that sometimes lobar pneumonia preceded lobular pneumonia. He thought that the question of the pneumococcus as the cause of pneumonia was not quite settled yet, as the coccus was found in other conditions. He dwelt on the varieties of pneumonia, insisting on an epidemic form.

Dr. W. S. FENWICK (London) said that at the commencement occasionally there was violent abdominal pain, in cases where the pneumonia started low down in the lung and the accompanying pleurisy affected the diaphragm. He quoted one case attended by severe opisthotonos, suggesting

meningitis; on the third day there was a patch of consolidation in the lung and as this cleared up the child got well. Another method of onset was by acute gastro-intestinal catarrh. For this he gave a bad prognosis, those cases starting in this fashion being generally fatal. The prognosis of pneumonia was difficult in children; those cases wherein a rapid distension of the bowel took place were nearly always fatal.

The PRESIDENT (Dr. F. TAYLOR of London) said that if they believed, as was customary now, that pneumonia was due to the infection by a toxin, they need not be surprised at the varieties of the disease. He had had two cases (not in children) where there was most severe abdominal pain at the onset of acute pneumonia; also, dealing with the question of contagion, he mentioned that he had seen four or five children attacked almost simultaneously by pneumonia, several years before the last invasion of influenza, and he considered this due to a contagious cause in all probability. He would agree to allow that the conveyance of contagion from one person to another must be very rare. He could hardly agree with the idea of the toxins being eliminated by the lung, as the fibrin exuded into it was not all expectorated but mainly absorbed. He then dealt with the question of high type and low type and the different varieties of pneumonia. Generally speaking, if the patches were large it was lobar pneumonia, if small lobular. He described three types of temperature: (*a*) that of the sudden rise, level, and sudden fall; (*b*) long oscillating temperature lasting two or three weeks; (*c*) short oscillating temperature ending on the fifth or sixth day.

Dr. T. D. LISTER (London) had examined many cases of broncho-pneumonia in children and post mortem he had never failed to find the pneumococcus. Sometimes the staphylococcus also was present. The consolidation of the lung in children under two years of age was of the catarrhal type. In ordinary sero-fibrinous pneumonia the infection took place probably through the blood, in catarrhal pneumonia or broncho-pneumonia through the air-passages or by direct extension of disease down the bronchi and tubes.

Dr. TIRARD, in replying, said that he would differentiate between capillary and vesicular bronchitis rather by whether the child died from asphyxia before the consolidation of the lung occurred. As he suggested the toxins were not eliminated by the lung and so they were retained and gave rise to symptoms. The comparative absence of physical signs in cases with cerebral symptoms explained itself by the poison retained in the blood causing the cerebral symptoms. His experience did not make him agree that apical pneumonia was generally attended by cerebral symptoms. He was also not at all sure that deferred physical signs were due to the spread of the disease from the centre to the surface of the lung. He commented on Dr. Nicholson's pulse studies and their value as giving suggestions for treatment. He considered that contagious cases of pneumonia were really cases of influenza followed by pneumonia. He would not consider an ordinary case of pneumonia in the ward in any way a source of danger. He concluded by thanking the meeting for their attention and congratulating the President on the good discussion which had been raised.

LARYNGOLOGY AND OTOLOGY.

WEDNESDAY, AUGUST 1ST.

The PRESIDENT (Dr. SCANES SPICER of London) read his address which was published in THE LANCET of August 4th (p. 369).—A discussion on

Intra-nasal Treatment in Ear Disease

was then opened by Dr. P. MCBRIDE (Edinburgh). He divided the subject into (1) the conditions of the ear liable to be affected by nasal changes, and (2) pathological conditions of the nose likely to involve the ear.—Dr. McBride was followed by Dr. CRESSWELL BABER (Brighton) and Dr. DUNDAS GRANT (London).—The discussion was continued by Dr. HERBERT TILLEY (London), Dr. JOBSON HORNE (London), Dr. WATSON WILLIAMS (Bristol), Mr. RICHARD LAKE (London), Dr. HOLBROOK CURTIS (New York), Dr. HEMINGTON PEGLER (London), and the PRESIDENT.—The openers of the discussion having replied the meeting adjourned. The time required for the discussion did not permit of any papers being taken.

In the course of the morning the section adjourned to that for Diseases of Children to take part in the discussion on a paper by Dr. J. THOMSON and Dr. LOGAN TURNER on the Causation of Congenital Stridor.

TROPICAL DISEASES.

WEDNESDAY, AUGUST 1ST.

The PRESIDENT, Colonel K. MACLEOD, called upon Dr. DUNCAN for his paper on

Quinine: its Action and Mode of Employment.

Dr. ANDREW DUNCAN, I.M.S. (ret.), opened the discussion on this subject by reading a paper in which he dealt with the several opinions declared by medical men of many nationalities. French observers generally were of the belief that in the milder form of malarial fevers quinine was valuable as a prophylactic but that in the pernicious form it was well-nigh useless. The Austrians and Russians found no advantages from the use of quinine as a prophylactic. In India several observations had been made on this subject; as an example at Peshawur in 1886 during the autumn 1203 men took quinine with an admission of 10·22 per cent. for malarial fever, whilst among 1202 men who had no quinine the admission rate for malarial fever was 27·28 per cent. During the Ashanti War of 1873 no good results were notified from taking quinine as a prophylactic and the same was recorded during the Ashanti War of 1896. An investigation on this subject was instituted on the West Coast of Africa by Mr. Chamberlain on the recommendation of Dr. Manson, with the result that quinine was considered as an efficacious protection in 87·7 per cent. of the cases tested. Dr. Duncan contrasted the action of several other drugs with quinine. Of these arsenic, nim bark, berberis, narcotine, kreat, and inderjas were the drugs employed, but the action of all was inferior to that of quinine in the time they took to effect a cure. Dr. Duncan believed that quinine probably acted by destroying the malarial organism.

Major W. J. BUCHANAN, I.M.S., superintendent of the Central Jail, Bhagalpur, Bengal, communicated a paper on the Prophylactic Issue of Quinine: a Synopsis of an Experiment on a Large Scale in Indian Jails. He discussed the arguments for and against the so called "prophylactic issue" of quinine. In 1894 the experiment of giving daily or several times a week a dose of quinine or cinchonidine to every prisoner was tried in the Punjab. During the year the experiment was tried the sickness and mortality rates for the Punjab jails were so good that it seemed as if the good results were to a great extent due to the issue of quinine.

Dr. FIELDING-OULD (Liverpool) read a paper on the Administration of Quinine with Special Reference to the Practice on the West Coast of Africa. He was of opinion that the beneficial action of quinine was due to the death and subsequent disintegration of the malarial parasite caused by the use of the drug and to the fact that quinine bound more closely to the hæmoglobin the oxygen present in it. Blood rich in malarial parasites but strongly impregnated with quinine was incapable of causing malarial infection when injected into a healthy person. Dr. Fielding-Ould objected to the use of the word "prophylactic" as applied to the exhibition of quinine. The drug could not prevent malarial infection but only attacked the parasites that were in the blood in a certain stage of their development. Unless young amœbulæ were present in the blood quinine could only do harm. In regard to treatment quinine was the sheet-anchor and might be administered by the mouth, by the rectum, or hypodermically, as occasion served.

The reading of these three papers was followed by a discussion.

Dr. PATRICK MANSON (London) remarked that quinine could only exercise its therapeutic action on the blood of persons residing in malarial infected countries when the parasite was present in the blood. To arrive at a scientific conclusion concerning the prophylactic use of quinine it would be necessary first to ascertain the kind of parasite present in the locality and then to administer the drug, as in the milder forms of malaria quinine was no doubt both prophylactic and curative, but in the pernicious forms its power was uncertain. Dr. Manson considered it important to ascertain the condition of the digestive organs before administering the drug, as in gastro-intestinal catarrh to give quinine by the mouth was to court disappointment in its action.

Lieutenant-Colonel MARSDEN, I.M.S., said that he had invariably given quinine both as a prophylactic and as a

therapeutic agent and the results were nearly always satisfactory. He mentioned one case of hæmoglobinuria positively traced to dosage with quinine, but he had only seen one case in 20 years' experience.

Mr. D. C. REES (London) gave his experience of quinine used as a prophylactic in Nigeria. He found that quinine given in five-grain doses daily, although it did not afford marked prophylaxis, served to lessen the severity and also the case-mortality of the attacks.

Dr. C. F. HARFORD-BATTERSBY (London) gave his personal experience of the use of quinine in Central Africa and came to the conclusion that it was highly efficacious. He had not seen any ill-effects from its administration.

Major E. WILSON, R.A.M.C., stated that in the Ashanti Expedition of 1895 quinine was tried for a time as a prophylactic and was discarded. He did not believe in heroic doses and had never seen blood in the urine after taking quinine.

Dr. B. S. RINGER (Canton) recorded a case in which complete blindness resulted from quinine taken in large doses. The patient, however, recovered the sight completely under iodide of potassium.

Lieutenant-Colonel MAITLAND, I.M.S., asked for information concerning treatment by methylene blue. He had had good results in his own practice from its administration. He stated that he had given quinine to pregnant women without any untoward effects.

Mr. JAMES CANTLIE (London) brought forward a case in which quinine was administered to a child aged four months by giving four grains thrice daily to the mother who was herself nursing the child and a quarter of a grain to the child with satisfactory results. He asked for information concerning the efficacy of giving the mother quinine as a means of treating fever in a child whom she was suckling.

Dr. HENDERSON (Shanghai) considered the administration of quinine to pregnant women as very likely to cause abortion. He advised opium to be given with the quinine if the state of the patient demanded quinine in the pregnant state.

Major RONALD ROSS, I.M.S (Liverpool), stated that he believed that a "secondary" fever occurred in old malarial cases, due probably to enlargement of the liver and spleen. The fever was of a continued type, was not directly due to the parasites, and was not amenable to quinine.

Dr. GUTHRIE RANKIN related a case where hæmoglobinuric fever developed in a young man in 14 months after proceeding to Central Africa. The patient had never taken quinine as a prophylactic. When he returned to Africa he took quinine as a prophylactic and had no return of the disease during a residence there of two and a half years.

Lieutenant-Colonel OSWALD BAKER, I.M.S. (ret.), was of opinion that the prophylactic dose of quinine was usually too small and advised the same dosage for prophylaxis as for curative purposes.

The PRESIDENT strongly advocated Dr. Manson's view that the nature of the parasites infecting the blood should be ascertained before or during the administration of quinine. Koch recommended microscopical examination as a means of detecting malarious infection in a community as parasites might exist in the blood without pyrexia; this, although a laborious means of dealing with the disease, was necessary if the attempt was to be made to get rid of malaria by giving quinine.

Lieutenant-Colonel J. MAITLAND, I.M.S., read a Note on the Etiology of Filariasis. The discovery of the filarial parasite in the proboscis of the mosquito by Dr. G. C. Low of the London School of Tropical Medicine was not, in his opinion, conclusive evidence that filarial disease was spread by the bite of the mosquito. He was of opinion that it was a water-borne disease in all probability, and he ascribed the immunity of Europeans in the tropics to filarial infection to the fact that they drank boiled or filtered water.

A paper was communicated by Captain J. P. JAMES, I.M.S., on the Metamorphosis of the Filaria Sanguinis Hominis in Mosquitoes, especially with reference to its Metamorphosis in the Anopheles Rossii and other Mosquitoes of the Anopheles genus. Captain James was of opinion that the period of filarial metamorphosis in the mosquito had hitherto been stated at much too short a time. He held that in those cases in which seven days had been stated as the period required, the idea had likely arisen from the fact that the mosquitoes had bitten a filarial infected person before the observations were commenced.—Dr. MANSON and Mr. REES took part in the discussion, the latter stating that some species of mosquitoes served better as hosts for the filaria than others. He believed, in opposition to both Dr. T. L. Bancroft and Captain James, that the filaria nocturna cast its sheath in the mosquito's stomach before penetrating to the thoracic muscles.

Major BUCHANAN, I.M.S., communicated a paper on the Hot Weather Diarrhœa of India in which he described a form of "choleraic diarrhœa" in India similar to cholera nostras and the summer diarrhœa met with in England. He was of opinion that in India, as in England, non-infected cases of intestinal flux might occur during the hot weather.

Dr. GEORGE THIN (London) communicated a note on a case of Blackwater Fever (with specimens). The paper was based upon the results of an examination of organs and tissues which had been sent to him from Central Africa by Dr. Douglas Gray from a patient who died from hæmoglobinuric fever. The patient had always used a mosquito net. The specimens showed melanin in the spleen, in the liver, and in the kidneys, and in the case of the kidneys degenerative and destructive changes in the secreting epithelium of the tubules as well. Dr. Thin was satisfied from the appearance of the organs that the patient had died from acute malarial fever in which the hæmoglobinuria was a concomitant symptom, and although the parasites were absent in the tissues of the spleen, liver, and kidneys the fact did not militate against this view.—Dr. MANSON and Mr. REES joined in the discussion and Mr. Rees stated that from an examination of the organs of this patient he had come to a conclusion opposite to that arrived at by Dr. Thin.

Dr. ANDREW DUNCAN read a paper on the Diseases of Goorkhas. A form of malaria peculiarly resistant to quinine was prevalent amongst Goorkhas. Phthisis, mumps, and measles were prevalent amongst soldiers in the Goorkha regiments, but enteric fever was almost unknown. The married men in the Goorkha regiments were liable to ophthalmia caused by the way in which the married women shut up their houses and from the insanitary nature of their surroundings.

THE NAVY, ARMY, AND AMBULANCE.

WEDNESDAY, AUGUST 1ST.

The meeting opened with an address from the President which will be found at p. 371 in THE LANCET of August 4th. Inspector-General NINNIS'S address was followed by papers chiefly interesting to those engaged in the organisation of field and base hospital arrangements and the composition and *personnel* of the various corps and companies needed for removal of the wounded from the battlefield to the hospital, their services as first aid, and their subsequent care of the wounded and sick in hospital.

The first paper put down to follow the address of the President was one by Surgeon-General J. B. HAMILTON,

On the Past, Present, and Future of the Royal Army Medical Corps,

but was postponed owing to the unavoidable absence of Surgeon-General HAMILTON, and the secretary, Surgeon-Captain JAMES HARPER, V.M.S.C., read instead a paper for Surgeon-Lieutenant-Colonel J. E. SQUIRE, V.D., who was absent from the meeting. The paper was entitled

On the Augmentation of the Royal Army Medical Corps for War.

It reviewed briefly the present composition and arrangements of the Royal Army Medical Corps, its difficulties as regards adequacy of *personnel*, and pointed out how such necessary augmentation should be carried out. The author deprecated the employment of civilians intermixed with the regular forces of the Royal Army Medical Corps as tending to be subversive of discipline, as there would arise great laxity, as he no doubt supposed was the case now in South Africa. He then proceeded to point out that the civilian and auxiliary medical assistants should have such training as would entitle the War Office to call upon them from time to time with that confidence in their training and powers of maintaining discipline which a knowledge of their previous partial training would impart to the authorities.

The above paper was followed by a paper by Brigade-Surgeon-Lieutenant-Colonel GILES, V.D.,

On Volunteer Medical Organisation.

The following discussion on these two papers took place.

Mr. TREVES (London), late consulting surgeon to Her Majesty's Forces in South Africa, said that with reference to

the question of transport raised by these gentlemen in their papers it appeared that there was an impression in this country that the medical department in South Africa was deficient in transport. Now, every hospital of 100 beds had its own transport. It was very difficult indeed to make a field hospital mobile. Hospitals composed normally of 300 beds had been suddenly swelled into hospitals of 800 beds as the result of sickness, fever, &c. There was, therefore, the natural result that transport for the latter would, of course, seem inadequate, as that for a small hospital had to do duty for a larger one. Nevertheless, this most unprecedented demand on the resources of the department had been well met and the hospital work was done most efficiently. Judging from experience of the campaign in South Africa it seemed that it would be a distinct advantage if a large hospital followed an army in the field, with its situation somewhere near the general's headquarters. With regard to the working of the civilians, medical men, nurses, orderlies, &c., in South Africa, there was a distinct misconception as to their not pulling with the members of the regular forces. Everyone worked cordially for the success of the medical arrangements, and there was the utmost generosity and cordiality displayed on all sides by everyone, and whether in field or in hospital the utmost harmony prevailed. The orderly himself as an individual was an incredible difficulty. Nurses could not go into a field hospital, though the nurses worked splendidly at Colenso. He (Mr. Treves), through the great courtesy of the War Office, was himself provided with splendid transport and relays of horses and mules. He was thus able to take two nurses up country. Nevertheless, the nurses ought not to go beyond the base hospital. The orderly must therefore be depended upon. At present, as he is, he is an impossible person. He was neither man nor woman; he had to pitch and strike tents, dig trenches, act as porter, and then, perhaps, be called upon to assist at an abdominal section. Water being so scarce as it was in South Africa it frequently occurred that surgical cleanliness was not always as it ought to be, nor could it be carried out. The burning questions were, How could they obtain proper orderlies, what prizes could be given to induce proper and suitable men to come forward, and what could be done to induce them to enter the army? The formation of a reserve of properly-trained orderlies, bearer companies, and medical reserve ought not to present any difficulty. Young medical men, of whom there were a great many suitable from among those obtaining qualifications, might serve three years, one year with the colours and two years in the reserve. By the above methods he thought that the Royal Army Medical Corps, already so efficient, could be made as perfect as it was possible for human efforts to effect.

Surgeon-Major G. A. HUTTON (Leamington) said it was a wonderful thing that the Director-General could lay his hands on from 400 to 500 civilian medical men and 1500 St. John Ambulance Corps men. He wished to corroborate Mr. Treves as to the efficient manner in which the War Office and the medical department had carried out what was required of them. They must all remember that they were only human institutions and as such they could only hope for that degree of human perfection which was reasonable. He himself had been told by generals and those in authority that the Royal Army Medical Corps was splendidly represented and was most efficient. Under the circumstances more than was done was humanly impossible.

Dr. FORBES ROSS (London), speaking entirely as a civilian medical member, but from a public health point of view, wished to call attention to a point which might tend to clear up a great deal of the supposed neglect. If after such a sojourn as the troops had at Modder river, followed by exposure and continuous fighting on short rations, typhoid fever broke out, it was entirely an unforeseen matter. Now, if 10,000 men had an attack fever-rate of 5 per cent. this would give 500 enteric fever patients. This would require 500 beds and, from the nature of enteric fever, the changing of 500 pairs of sheets and blankets daily, and in addition these must be disinfected, for they were a distinct source of danger if not properly washed and stoved, for they would act as means of disseminating enteric fever among the wounded and other sick. It might also be looked at as a blessing that beds and bedding were not to hand, as by this means alone a terrible epidemic much worse than the present one might have been started. He advocated the digging of the ground over a surface of about six feet by two feet six inches, the soil thus disturbed to be broken up and raised six inches from the surrounding ground; this when spread with a waterproof sheet would provide a comfortable bed and could be changed from time to time and needed no such extensive transport as would the projecting of the amount of hospital equipment desired by those persons who forgot that this was primarily a war and not an expedition fitted out for the express purposes of treating enteric fever *al fresco* on the veldt, and ought therefore to have been equipped regardless of expense and transport, needed or available.

Surgeon-Captain J. CANTLIE, V.M.S.C., then contributed a paper on

How to Link the Militia, Yeomanry, and Volunteer Medical Services with the Royal Army Medical Corps.

He advocated the bringing into line of the Volunteer, Militia, and Royal Army Medical Corps, to do away with the word "staff" as applied to the Volunteers, and have all the branches designated as "Medical Corps." He would have the men in any of the branches freely interchangeable for purposes of service and augmentation of the Royal Army Medical Corps. Among other things he deprecated the training of medical students along with and at the same time as the men of the bearer companies, for it was not proper that these future officers should occupy this position. In no other service were the cadets compelled to go through a similar experience.

This paper was followed by a paper by Brigade-Surgeon Lieutenant-Colonel G. S. ELLISTON, V.D., on

Brigade Bearer Companies.

He recounted the troubles and difficulties he went through, and the organisational difficulties experienced in order to bring the *personnel* of the medical staff as regards training to their proper state of efficiency.

These two papers were discussed by the following gentlemen:—

Surgeon-General J. B. HAMILTON said that Surgeon-Captain Cantlie's paper brought to mind the regretted loss of the Militia Medical Service of the army. That loss was the greatest possible blow to the army. There was a loss of men with good county connexions who did recruiting work well. No one now took their place. Only two per 1000 medical officers in the militia would have been a great help in South Africa. Every officer of a militia battalion got 4*s.* per diem with the exception of the militia medical officer, but this had now been remedied. The auxiliary branches were too scattered. The Army Medical Reserve was the greatest possible humbug which was ever started. A member could wear a uniform, but when called upon for service he would hardly leave a good practice to accept £270 per annum. In the past men could not be got to train for bearer companies. The proper thing would be to have bearer companies separate from the regiment. They must form a reserve of nurses, but that proposal made by him some years ago was sat upon by the War Office, but now they were coming round in this matter. The increase of the Royal Army Medical Corps could be done by the reconstitution of the Militia Medical Service and amalgamated and employed with them if necessary. Put them in a simple uniform and recognise their rank and position.

Surgeon-Major G. A. HUTTON made a few remarks on the number of militia officers now with the forces.

Major E. M. WILSON, C.M.G., D.S.O., said that militia officers were doing excellent work side by side with the Royal Army Medical Corps.

Surgeon-General T. F. O'DWYER, Principal Medical Officer of the Aldershot District, said that volunteer bearer companies were recognised and encouraged by the War Office. Their training was not satisfactory. There should be more attempts to train them in hospital duties; at present they were only trained in first aid and field duties. They should be encouraged to present themselves at the hospitals to be trained. It was unpleasant to say some things, but he was afraid many volunteers only looked upon training as a picnic. The volunteer brigades had five days' training but during that five days they learned nothing. Some few who had come to hospital for training liked it and took pleasure in it. Medical students were not desirable members of bearer companies. The civilian element was better than

persons who might afterwards become members of a superior branch of the service, as medical students often left when most efficient. Militia surgeons must be properly trained if they were to be introduced again.

Brigade-Surgeon Lieutenant-Colonel ELLISTON, V.D., said that brigade bearer companies carried out hospital duties in his department. Only last Tuesday he had 10 cases of heat-stroke and was able to provide an orderly for every case separately. The men were most efficient and this was the case with those whom he had sent to South Africa.

Surgeon-Captain J. CANTLIE proposed the following motion as the outcome of his paper:—

That the Navy, Army and Ambulance section request the council of the British Medical Association to appoint a committee to draw up a scheme to be forwarded to Government for the reorganisation of the medical services of the auxiliary forces on the basis of the system of the Royal Army Medical Corps and for the purpose of bringing the medical services of the regular and auxiliary forces into unison.

The motion as first proposed limited the committee to five members, but on the motion of Surgeon-General J. B. HAMILTON the limitation of the committee to any particular number was dropped and the motion was unanimously passed as above.

Surgeon-Captain J. HARPER, V.M.S.C., said that it was most difficult to get up *esprit de corps* among the men of a bearer company, and unless this was done no good could be done with the men. This he had tried to do with a good deal of success. He had now 20 very efficient men with the Yeomanry in South Africa.

Brigade-Surgeon G. KING also spoke.

THE ANNUAL MUSEUM.

(*Continued from p. 374.*)

II.—FOODS AND FOOD PRODUCTS.

No very novel departure could be noted in regard to special foods. One feature, however, consisted in the number of special milk preparations and milk products that were shown. During recent years strong endeavours on all sides have been made to separate the nutritious constituents of milk without injuring their nourishing properties. As a rule proteids undergo some change in the course of separation which affects their original food value, but in this direction certain successes obviating this deterioration have been met with, judging from the good physiological results obtained on administration of the proteid so separated.

Turning to milk itself there were several stalls devoted to modified specimens of this natural food which have been called into request by the teachings of modern physiological and bacteriological inquiry. No better examples of so-called humanised milk, sterilised milk, with and without cream, modified milk, &c., could be mentioned than those shown by the Aylesbury Dairy Company, Limited, who evidently conduct their business on strictly scientific lines, retaining for that purpose both chemical and bacteriological experts. Indeed, this company are prepared to supply pure milk foods exhibiting a composition in accordance with that which the medical practitioner may desire to prescribe. Of condensed milk there were several well-known brands and it is satisfactory to note that special care is taken to secure a maximum of cream in the concentrated product. The Anglo-Swiss Milk Company of 10, Mark-lane, London, E.C., exhibited amongst other things specimens of their Ideal milk which is unsweetened and sterilised and which contains a proportion of fat consistent with the degree of concentration. Besides concentrated milk Mr. Henri Nestlé of 48, Cannon-street, E.C., brought to the visitors' notice a food the composition of which shows it to contain all the elements necessary for the sustenance and growth of infants. It is worth while adding that this exhibit included also a condensed milk without the addition of sugar. The proportion of fat contained in the condensed milks of this firm is the maximum. Dry milk products were represented at several stalls. That of the Plasmon Syndicate, Limited, of 56, Duke-street, Grosvenor-square, W., attracted considerable interest, since Plasmon appears to be separated in such a way from milk as to leave the nutritive properties of the proteid unimpaired. Analysis shows plasmon to consist of the casein and albumin of milk together with the milk salts, the whole being soluble in water. According to Virchow, plasmon is not in any degree inferior in nourishing value to that of its equivalent of proteid in milk. It would thus appear that plasmon, which practically consists of the separated proteids of milk, loses no fraction of its nutrient value in the course of separation. Yet another milk product is "Protene" of the Protene Company, Limited, 36, Welbeck-street, S.W. This is again the proteid of milk separated by a special process. It provides an excellent adjuvant to most foods, raising to an important and certain degree their flesh-forming equivalent. The preparation has been analysed by ourselves, and the report appeared in THE LANCET of Nov. 5th, 1898 (p. 1207). Among the interesting preparations shown at this stall were some diabetic foods enriched with "protene," but practically free from carbohydrates while palatable to the taste. "Tropon" (Messrs. Arthur Reiner and Co., Dashwood House, Old Broad-street, London, E.C.), which is described as a natural pure albumin, is of course a product related to the separated proteid of milk, since it contains approximately the same proportion of nitrogen. We have described it fully in our analytical columns, but we may add that it forms an excellent adjuvant for enriching foods, more especially in regard to their nitrogenous value. On the other hand, "Somatose" of the British Somatose Co., Limited, of 165, Queen Victoria-street, London, E.C., is a digested albumin containing true proteoses. It is soluble in water and being a normal product of gastric digestion is readily assimilated. It may be used with advantage in conjunction with most foods and is well adapted for this purpose since it is practically tasteless. Somatose occurs combined with iron, a combination which admits of the administration of iron without gastric disturbance. The interesting dietetic products of Messrs. Fairchild Brothers and Foster of Snow Hill Buildings, London, E.C., are well known. On the present occasion the exhibit included "Pepsencia," an agreeable fluid with marked digestive properties owing to the presence of gastric enzymes extracted directly from the peptic glands. Again, "Panopepton" is prepared by an ingenious process whereby its constituents, derived from beef and wheat flour, are digested and therefore are presented in an easily assimilable form. This firm's peptogenic milk powder is designed for the purpose of extemporising fresh humanised milk in the home. Analyses have shown that by adding peptogenic milk powder to cows' milk in the proportions directed a product is obtained in remarkable conformity with the composition of human milk. The exhibit included pure "Pepsin" and "Trypsin" as well as "Zymine powders" for the preparation of peptonised milk. Messrs. Van Abbott and Son, of 104, Wigmore-street, Cavendish-square, London, W., presented to view an excellent assortment of foods for invalids and for diabetics and dyspeptics. It is remarkable with what success this firm has been able to prepare foods minus carbohydrates which yet are palatable and acceptable. The exhibit also included some nutritive beef biscuits which contain 20 per cent. of mosquera beef meal, with its finely divided fibre and unaltered albumin and peptones. The biscuits therefore are highly nutritive. In a kind of annexe Messrs. Callard and Co. of 65, Regent-street, London, W., occupied a stall devoted to diabetic foods and certain other prepared foods suitable for those burdened with obesity or troubled with gout and indigestion. Lastly, diabetic marmalade is an excellent acquisition amongst the special foods which have comparatively recently been introduced by this firm. Nearly opposite was an excellent assortment of specialities for invalids on the stall of Messrs. Brand and Co., Limited, of 11, Little Stanhope-street, Mayfair, London, W. Besides the essences of beef, mutton, veal, and chicken, this firm showed a meat juice which is derived from meat in the cold and therefore represents the most nourishing portion of this animal food. An excellent way of administering this meat juice is to mix it with effervescing mineral water. The assortment comprised a very valuable series of special foods of animal origin. An important novelty in the direction of foods is "Marvis," which is described as the new fish food consisting of a dry white powder with a pleasant fresh smell of fish which yields a soup of undoubtedly nourishing value and very palatable to the taste. The process of preparation is evidently conducted with care, since the product possesses a delicate flavour of the fish which is so generally spoilt by transit. This interesting departure is being undertaken by the Patent Fish Food Syndicate of Upper Greenock. A useful food adjunct is "Albene," a vegetable fat which has been carefully refined. For cooking purposes it is an excellent substitute for butter, as it is not

liable to change and is odourless and tasteless. This preparation appears to offer certain advantages of undoubted importance in the cooking of food which call for special remark. This attractive-looking fat is prepared by Messrs. Broomfield and Co. of 83, Upper Thames-street, London, E.C. Messrs. Cadbury Brothers, Limited, of Bourneville, near Birmingham, showed several of their noted preparations, the basis of which is pure cocoa made from high-class bean and containing absolutely no "additions." Whatever definition may be adopted as to what is pure cocoa Cadbury's cocoa will be certain to be placed well within the mark. Mellin's food for infants and invalids is well known, the feature of this food being that the starches derived from the several cereal grains are modified by diastase, which fact is much in favour of the digestibility of the preparation. The exhibit of the company (Mellin's Food, Limited, Marlborough Works, Stafford-street, Peckham, London, S.E.) included also some "food biscuits" containing a high proportion of soluble nutritives and a cod-liver oil emulsion finished in such a physical condition as to promote the easy absorption and assimilation of the powerful tonic and nutrient agencies which cod-liver oil is known to contain. A very interesting series of special foods was exhibited by Bovril, Limited, of 152–166, Old-street, City-road, London, E.C. These preparations are so well known as to call for little further remark. Mention, however, should be made of invalid bovril, which contains a rich proportion of unaltered albumin and is therefore a powerful nutrient and restorative for invalids; of bovril meat juice, which is expressed in the cold, an excellent sustainer; and of examples of the emergency rations and military foods used in the present campaigns. Virol, Limited, is now associated with the Bovril Company, the virol products being more strictly set apart for special medical requirement. Thus, virol is a powerful food and tonic because it is easily assimilated and is composed of rich food-forming material, red bone-marrow, &c. The excellent meat preparations of Liebig's Extract of Meat Company, of 9, Fenchurch-avenue, London, E.C., serve to adorn the stall of this company and trial prepared dishes were offered to the visitors. The Liebig Company's extract of beef has become such a household expression that the new word "Lemco" now adopted for the preparation should be generally known. Besides the ordinary extract now thus designated "Peptarnis" is worthy of notice. As our analysis has shown this consists mainly of peptone of a palatable, highly nourishing, and, of course, digestible character. It is a powerful restorative and food, ministering considerably to patients who have undergone loss in weight through enfeebled digestive conditions. An interesting series of foods was shown by the Worth's Food Syndicate, Limited, Cheltenham. These consisted of cereal foods more or less modified by cooking and thus rendered more soluble and easy of digestion. Though this preparatory process is an advantage in regard to foods for the dyspeptic or the invalid or the infant, yet it does not render, as is asserted, cereal flour suitable for the use of the diabetic, since the proportion of carbohydrate is absolutely unaltered by this process. The stall of Messrs. Scott and Bowne, Limited, of 95, 96, 97, and 98, Great Saffron-hill, London, E.C., was devoted to the exhibition of the various constituents concerned in the production of their cod-liver oil emulsion. We have already shown in our analytical columns that the composition of this emulsion is based on the known requirements of an enfeebled state of health and the oil occurs in the physical condition of an emulsion which secures its assimilation. The pioneer of all malt extracts was undoubtedly M. Hoff of Hamburg and of 29, New Bridge-street, E.C. This extract, though not concentrated, contains all the peculiar and valuable dietetic properties of barley malt. It is hardly distinguishable from ordinary stout except that it is quite free from undue acidity and possesses a rich malty taste and is much more digestible. Messrs. Keen, Robinson, and Co. of 6, Garlick-hill, Cannon-street, London, E.C., exhibited specimens of mustard preparations the excellence of which has long been associated with the name of this firm. In addition they showed their patent barley and patent groats, both of which preparations are undoubtedly nutritious, containing a maximum proportion of the flesh-forming and bone-forming constituents of barley and oats respectively. The patent barley prepared in the form of "Barlikos" affords an excellent hygienic summer drink. Cereal preparations were also the feature of the exhibit of the Infant and Invalid Co., Cereal Buildings, 54, City-road, London, E.C. The most important of these, perhaps, is the "I and I Food," prepared from the best of cereals and rendered more easy of assimilation by the conversion of some of its insoluble constituents into soluble constituents. The albuminoids and fat are in such excellent proportion as to indicate the selection of several kinds of cereal flour and a judicious mingling of them.

It must be admitted that the exhibition of foods and food products this year was not so representative in character as on previous occasions, nor were the exhibits under this section as great in number.

THE FIRST INTERNATIONAL CONGRESS OF THE MEDICAL PRESS HELD AT PARIS, JULY, 1900.

(FROM OUR SPECIAL CORRESPONDENT.)

THE NATIONALITIES REPRESENTED.

THE third and last day of the Congress proved by far the most important and critical. This was Saturday, July 28th, and as the International Congress of Deontology had concluded on the previous evening I was now able to attend. On entering the great amphitheatre of the École Pratique de Médecine I found that there were about 40 out of the 168 members of the Congress present. The British contingent consisted of one correspondent of the *British Medical Journal* and two members of the staff of THE LANCET. There were eight Germans, seven Belgians, five or six Italians, five or six Russians, three members each from Norway, the United States of America, Ecuador, and Mexico, two members each from Spain, Portugal, and Bohemia, and one member each from Switzerland, Greece, Denmark, Cuba, and Tunis. I should mention that Dr. C. D. Sutherland represented the *Indian Medical Journal*. Numerous honorary presidents had been elected: Dr. Podwyssotzki for Russia, Dr. Schonberg for Norway, Dr. Valdez for Spain, Dr. Ehlers for Denmark, and Dr. Squire Sprigge for Great Britain; but the real and ruling president was Professor Cornil, assisted by Professor Charles Richet and the general secretary, Dr. Blondel.

THE MEDICAL PRESS IN GREECE, CUBA, AND BELGIUM.

The proceedings were opened by Dr. FONSTANOS who gave a history of the medical press in Greece. He explained that previously to the formation of the Medical Society of Athens in 1836 the country was overrun by charlatans of every description. Many medical papers had been started, but the materials were so slight and the number of medical men so limited that for the most part they came to an untimely end. To-day the two principal papers were the *Medical Progress*, published in Greek, and the *Grèce Médicale*, published in French.

Dr. JUAN SANTOS FERNANDEZ followed with a description of the medical press of Cuba. The first medical paper published in the island appeared in 1840, but did not live long. In 1861 Dr. Gutierrez founded the Academy of Medical Sciences and published its *Annals*. Seven years later there appeared the *Gazette of the Medical Sciences*, which, however, was swept away by the revolution. In 1873 some new publications appeared, and of these the *Medical and Chirurgical Chronicle* survived and may now be seen at the Exhibition. In spite of the political convulsions from which the island of Cuba had so severely suffered the medical press of Cuba now worthily represented the progress of medical science.

Dr. EMILE GIBSON (Brussels) reported on the Belgian medical press and recalled the fact that the first newspaper published in Europe was issued by Abraham Verhoeven at Antwerp in 1605. As for medical papers, one of the first to appear was the *Journal de Chimie Médicale, de Pharmacie et de Matière Médicale*, issued in Belgium in 1825. But though it was a very cheap paper for want of subscribers it did not live long. To-day, on the contrary, there were so many subscribers that there were no less than 70 journals published in Belgium dealing with medicine, surgery, or hygiene, together with the reports issued by numerous polyclinics, especially at Brussels.

At the conclusion of this report Dr. PÉCHÈRE requested the Congress to protest against the gratuitous circulation of medical papers which receive a State subvention. There were

in Belgium scientific institutions which were protected by the Government, and these employed a part of the subvention they received from the State to issue journals which they sent gratuitously to medical men, thus competing against the independent medical press.—Professor CORNIL said that in France the published reports of the proceedings of learned societies which received subventions from the State were only sent to the subscribers, and such subscriptions were often higher than those paid for ordinary medical journals.—The Congress adopted a resolution condemning the subvention by the State of medical papers which competed against the other journals.

THE MEDICAL PRESS OF THE UNITED STATES AND OF GREAT BRITAIN.

Dr. C. W. FASSETT, editor of the *American Medical Journalist*, remarked that the first journal published in America was founded at the end of the last century and it contained principally articles translated from the French. Now there were 278 medical journals in the United States. The prestige of the medical press had been greatly enhanced by the Association of Medical Journalists, which was founded 15 years ago, and by the Association of Medical Publishers, which was founded in 1893. Dr. Fassett insisted that medical journals should avoid sensational news and the discussion of vague theories, and should be so written as to be understood by general practitioners who were not specialists. The American medical papers generally acknowledged quotations and were freely exchanged. Some papers would not insert advertisements of specialities unless the composition of the preparation was clearly indicated. He concluded by urging that the next International Congress of the Medical Press should be held at St. Louis in 1903, when the forthcoming great exhibition would take place.

A paper by Dr. S. SQUIRE SPRIGGE (London) on the British medical press was then read. He gave a history of the early struggles of THE LANCET and of the successful efforts of its editor to combat the nepotism prevalent at the hospitals and medical schools. The success achieved led to the foundation of many other journals, but the only paper which had survived and which could be compared by reason of its circulation and influence with THE LANCET was the *British Medical Journal*. Dr. Sprigge gave a short history of the development of this latter journal. The Congress was most interested when he described the financial situation of THE LANCET and the *British Medical Journal*, showing that the income of these papers rendered them quite independent and supplied them with means, which they employed freely, to make original researches and investigations, to depute experienced technicians to follow armies on the field, to study epidemics in all parts of the world, to analyse all sorts of food-stuffs, &c. The results of these independent and fearless investigations had largely contributed to reform the laws of the country as they affected medical education, public health, the adulteration of food, the housing of the poor, hospital accommodation, &c. Dr. Sprigge concluded by expressing the hope that charlatanism and *réclame* would be things of the past and that the medical journalist of the future would recognise but one master, the public good. The address was warmly applauded and was generally recognised as one of the most suggestive and interesting papers submitted to the Congress.

THE GERMAN MEDICAL PRESS.

Dr. SPATZ (Munich) then spoke about the German medical press. It was only towards the middle of the century that the need of such papers was felt. In the revolutionary period of 1848 Virchow had founded at Würzburg the *Medical Reformer*, but when he went to Berlin this paper collapsed. However, he soon issued his *Archiv für Pathologische Anatomie und Physiologie und für Klinische Medicin*, and from that day the development of the medical press in Germany had not ceased. In 1864 Dr. Posner founded the *Berliner Klinische Wochenschrift*, which was intended for all members of the profession throughout Germany. It was still the leading medical paper. The position of affairs in Austro-Hungary was much the same as in Germany, and the same articles, &c., were sometimes published simultaneously in both countries. The *Deutsche Medicinische Wochenschrift* first started the idea of forming an Association of the German Medical Press, and the rules of this association were very similar to those of the present Congress. The result had been a great improvement in the tone of the medical press of Germany.

THE REPRODUCTION OF SCIENTIFIC ILLUSTRATIONS.

This terminated the reports on the medical press of different countries and M. ALCAN then read his paper on the right of reproducing illustrations which I have already summarised.

In the discussion that ensued Dr. MARCEL BAUDOUIN argued that a drawing in a scientific publication should be considered as so much type. It was not a work of art; it was a hieroglyphic such as the Egyptians employed and the Chinese still use, and by which the author was better able to convey his meaning. As type could be reproduced so should the drawing or photograph which was published instead of words in type. With regard, for instance, to intestinal sutures there were some 600 drawings that had been published. Would the author of a book on the subject have to apply to the owners of these 600 illustrations? By slightly altering each design he could utilise them all and not infringe the law, but sometimes it was found that by altering the drawing it no longer agreed with the text. Then in a later edition the text was altered to make it agree with the drawing, so that in the end both drawing and text were false and incorrect. He thought that there should be greater latitude with regard to the reproduction of scientific illustrations.

Dr. REGNAULT remarked that as copyright lasted 50 years it sometimes happened that the author was dead and that his family could not be found or that the publisher was bankrupt and that his blocks and rights had been sold to no one knew whom. Publishers, he thought, should form an association like that of the society of authors so that there might be one single central place where all applications and payments should be made for the right to reproduce.

Professor RICHET remarked that the question was most complex because there could be no exact demarcation between a scientific and an artistic drawing. The latter was protected by the law of copyright. All they could do was to urge that, for the sake of scientific education, it was necessary to reproduce scientific drawings and leave to another Congress the task of formulating a scheme to facilitate such reproductions.

Dr. POSNER (Berlin) proposed to nominate a committee of three Parisian members to discuss this question with publishers, medical men, and legislators, and to study generally the question of literary property from the medical point of view. This committee would consist of Dr. de Maurens, Dr. Marcel Baudouin, and Dr. Blondel, who were well acquainted with the subject and held different opinions. This committee was thereupon elected.

THE RIGHT OF TRANSLATION AND OF REPLY.

Dr. PODWYSSOTZKI, on behalf of the Russian members, urged that the copyright in regard to papers published in periodicals should, so far as the translation of such papers was concerned, be limited to six years. Dr. JAYLE and Dr. PISTRE then reported on the right to reply. According to Article 13 of the Law of 1881 all persons mentioned by name had an unlimited right of reply. This was thought excessive, for replies might be converted into mere self-advertisements. The editor should be able to exercise his discretion; but a person whose reply had not been inserted might have the right to appeal to a tribunal which would judge whether the editor had acted unfairly.

Dr. J. NOIR then read a short paper enforcing the absolute necessity of forming an international association of the medical press, and the morning sitting concluded.

RÉCLAMES OR PUFFS.

It was at the very last sitting that the Congress ventured to tread on really delicate ground. First, Dr. G. LEVY complained that obvious puffs were written by persons who declared themselves to be medical men but gave fictitious names, thus shielding their reputation. He brought forward a motion stating

> That when the title "Doctor" was employed it should only be followed by the name inscribed on the diploma.

The Congress, however, thought that though this might be a good measure to prevent puffs, medical men who wrote articles that were not puffs were justified, so as to avoid self-advertisement, in adopting fictitious names. The discussion finally dropped without the adoption of any resolution.

Dr. ARCHAMBAND then moved

> That *réclames* and non-medical advertisements might be published in medical papers.

Without *réclames* many papers could not live and though a

réclame appeared as an article in the body of the paper everyone knew that it was paid for and was simply another form of advertisement.

Mr. ADOLPHE SMITH (London) energetically protested against this opinion. If *réclames* did not deceive anyone why were they paid for at a much higher rate than ordinary advertisements? Then it was not so much a matter of the publicity given in the one issue of the paper as the fact that what the paper had said might be reproduced and quoted on millions of labels and circulars. So far, however, as *bonâ-fide* advertisements were concerned there was no reason why a tailor or a coachbuilder should not advertise in a medical paper as well as a wholesale druggist, but all advertisements should be carefully supervised so that none should appear that were opposed to the ethics or interests of the profession.

The Congress voted by a large majority against the insertion of *réclames*.

FOUNDATION OF THE INTERNATIONAL ASSOCIATION OF THE MEDICAL PRESS.

Next came the report of Dr. LABORDE, concluding in favour of forming an International Association of the Medical Press, which was taken as read and which I have already summarised. Dr. POSNER (Berlin) argued that there should be an association of the medical press in each nation which should participate in the international congresses and that these congresses should be held frequently.

Dr. BLONDEL remarked that the local conditions of the various countries differed materially and that the Congress should first decide on the opportuneness of creating an international association. As for the statutes drawn up by Dr. Laborde they could only be considered as a scheme which it was not now necessary to discuss.

Dr. JAYLE, however, insisted that it was all very well to found an association, but they must first of all know who were going to be included in the association. Dr. Laborde, in his report, had said that the association should consist of directors, editors, and general secretaries of medical papers. Such a limited definition would have to be set aside before the proposal to form an association could be accepted, and there must instead be a distinct assertion that medical journalists were admissible.

Then followed a lengthy and at times a somewhat confused and disorderly discussion which I will not attempt to report. I will, however, try to explain the main points at issue. First we find here a good illustration of the fact that papers prepared for an international congress should be written in quite a different manner to that which is customary for a national congress. Internationally the same term has a very different meaning. In England the term "director" might be taken to mean the business manager who, as a rule, is neither a journalist nor a medical man. In France many medical papers belong to medical men who are at once managers, editors, and chief contributors of their own papers. Then the term "secretary" has no journalistic meaning in England, while in France it often means the sub-editor. On the other hand, our English word "editor" in France means publisher. These terms, therefore, in an international congress need explanation. It was, moreover, objected that if all medical journalists were admitted there were some 30,000 of them in France alone. Of course this was mere playing with words. A practitioner who once or twice in his life sends an account of a case that has come under his observation to a medical paper, for which contribution as a rule he is not even paid, cannot consider himself a journalist. As for the danger of the congresses being swamped by journalists, it is evident that no journalist would incur the expense of attending such congresses unless at least a considerable portion of his income depended on his pen. On the other hand, the proprietors and publishers of papers could more readily find the means of being present. Practically the discussion that took place was based on the question whether the proposed international association should really represent the medical press as a whole and all the interests involved, or be only an association of the owners of medical papers.—Professor RICHET protested that there was no desire to exclude journalists, but it was to be an association of employers and employed, whose interests were more intimately linked together than was generally supposed.—Dr. BLONDEL cordially endorsed this view, but wanted the details to be settled by a committee to be appointed or by future congresses.—Dr. JAYLE, on the contrary, insisted that the principle of the admission of journalists must be emphatically proclaimed now at once. Finally, Professor CORNIL put Dr. Blondel's proposals to the vote. They are worded as follows:—

> The statutes of this international association shall be submitted to the next International Congress of the Medical Press. They shall be prepared by an international committee appointed for that purpose. The members of this committee shall be elected in each country which possesses an association of the medical press convoked for that purpose. The committee of the present Congress shall act temporarily as the intermediary between the various sectional groups that have to constitute the definite international committee.

As this motion did not speak of journalists 13 members voted against it and 25 in its favour. But now Dr. JAYLE maintained that his proposal did not run counter to the resolution which had been carried and he moved it as an addendum.—Professor CORNIL agreed and thought that the Congress might now vote in favour of admitting medical journalists as members of the proposed International Association of the Medical Press, and this was adopted unanimously.

It was then decided that the second Congress should meet next year in Brussels. This with the usual vote of thanks completed the proceedings and the Congress separated, well satisfied at having established an International Association of the Medical Press. The general secretary, Dr. R. Blondel, has worked very hard to bring about this result and was naturally and warmly congratulated. In the evening the members of the Congress met at the Auberge des Nations in the Old Paris Street of the Universal Exhibition. The banquet was presided over by Professor Virchow of Berlin, and many toasts were drunk and great cordiality prevailed.

Paris, August 5th.

HEALTH CONGRESS IN ABERDEEN.

THE annual congress under the auspices of the Royal Institute of Public Health took place this year in Aberdeen. The joint Town and County Hall, which was used for the issue of tickets, was opened on Wednesday, August 1st, but the actual business did not commence till August 2nd. The general and sectional meetings were held in Marischal College buildings and extended to August 7th. Between 800 and 900 delegates from various sanitary and municipal authorities in the United Kingdom attended.

THURSDAY, AUGUST 2ND.

The general inaugural address was delivered in the Mitchell Hall by the President of the Congress, the Earl of ABERDEEN, Lord Provost FLEMING occupying the chair. Lord ABERDEEN, after alluding to the assassination of King Humbert and the death of the Duke of Saxe-Coburg and Gotha, dwelt upon the improvements brought about by sanitary reformers and called particular attention to the success of the district nursing system. At a later hour the presidents of the various sections delivered their opening addresses.

In the Section of Preventive Medicine and Vital Statistics the President, Professor W. J. R. SIMPSON (King's College, London), chose as his subject Administration and Research in Preventive Medicine. Professor Simpson, after urging the necessity of establishing a special sanitary service for India and an Imperial or Colonial sanitary service generally, adverted to the sanitary changes in Aberdeen, of which city before proceeding to Calcutta, he was medical officer of health. He then pointed out that in the bacteriological branch of preventive medicine Great Britain was not, as in other branches, in the first rank, and the absence, he said, of well-endowed laboratories for scientific research, either connected with their universities or colleges or as separate institutions, was a fatal defect in their otherwise excellent sanitary organisation. He then referred to the preparation of curative and prophylactic serums and said that investigations into comparative parasitology had also contributed much to preventive medicine and had revolutionised their ideas of malaria. The discovery of the parasite of malaria and its developmental stages in the mosquito permitted them to brush aside all vague generalities concerning the disease and the conditions which produced it. Professor Simpson concluded by referring to the question of sanitary supervision in the South African war. While expressing respect for the magnificent work done by the Royal Army Medical Corps, he said there was evidently pressure when two medical officers were required to do the work of four. This defect in their

system should be remedied at once, especially in view of the large number of troops going to China who would be exposed to much worse conditions than those in South Africa. A specialisation in the function of different departments of the Army Medical Service was required, and it was certain that without a special sanitary service disease in times of stress would not be prevented.—In the same section a paper by Dr. C. KILLICK MILLARD (medical officer of health of Burton-on-Trent) on the Notification of Measles was read in the absence of the writer and gave rise to a discussion which was taken part in by Professor W. J. R. SIMPSON, Sir CHARLES A. CAMERON, C.B. (executive sanitary officer, Dublin), and others.

The Section of Bacteriology and Comparative Pathology met in the Pathology Class Room under the presidency of Professor D. J. HAMILTON (Aberdeen University), whose opening address was on Recent Developments in Bacteriology and on the danger of spreading disease by vehicles of transport. As to tuberculosis they were all, he stated, agreed that there must exist a close relationship between the bacillus of leprosy and that of tubercle. With respect to typhoid fever Professor Hamilton remarked that the difficulty of recognising the bacillus in water still remained almost insuperable and that probably the method adopted by Hankin was the most to be depended upon for reliable results in the absence of the bacillus coli. Having referred to horse-sickness he then touched on the subject of cancer. As the evidence at present stood he was unable to form an opinion as to the parasitic theory. Cancer was a very common disease in Queensland, and the popular belief, supported by expert evidence, was that it was derived from cancerous cattle, the flesh of which was consumed in a half-cooked condition. Professor Hamilton then went on to protest against the apathy of railway companies in the matter of adopting precautionary measures against contamination and dust contagion from railway carriages. He urged the necessity for legislation on this matter, and at the same time he deplored the misery which was occasioned through the defective sanitation of schools and the evils caused by the condition of public resorts, which were rendered unhealthy through the neglect of the local authorities.—A short discussion followed, after which Professor E. F. TREVELYAN (Leeds) made some remarks on Pig Tuberculosis and showed specimens.—Dr. ALLAN MACFADYEN (director of the Jenner Institute of Preventive Medicine, London) also read a paper on the Detection of Tubercle Bacilli in Dairy Products.

In the Section of Chemistry and Meteorology there was but a small attendance. In his opening address Professor C. HUNTER STEWART (Edinburgh) devoted his remarks mainly to periodical recurrences of epidemic diseases and the meteorological conditions to which these had been attributed. After discussing the question of the carrying of micro-organisms in the air on particles of sand he pointed out the difference in the incidence of summer diarrhœa in the west of Scotland as compared with the east of that country, and alluded to the apparent connexion between the large quantity of carbonic acid in the ground air and typhoid fever. In conclusion he referred to the amount of organic matter contained in made-up soils, and urged the desirability of further investigation being made so as to ensure that the land was properly purified before being used as sites for buildings.—A paper prepared by Mr. EDWARD RUSSELL, F.I.C. (London), and Dr. A. E. PORTER (London) on an Inquiry into the Chemical and Bacteriological Condition of the Air in Board Schools was then read and gave rise to a discussion in which the artificial method of ventilation was generally condemned.—Mr. THOMAS JAMIESON, F.I.C. (city analyst of Aberdeen), then read a paper on the Effect of Organic Matter in Water on Health.

In opening the Section of Architecture and Engineering the President, Mr. JOHN HONEYMAN, R.S.A. (Glasgow), observed with respect to the construction of dwelling-houses that a point which was very much overlooked was the necessity of proper ventilation. He referred to the lack in cities of cheap houses for the poor.—A paper was read by Mr. JAMES SOUTTAR, F.R.I.B.A. (Aberdeen), on Architecture and Hygiene.—In a paper on the Architecture of the Twentieth Century Mr. BANISTER F. FLETCHER, A.R.I.B.A. (London), contended that public health would be the watchword of the new century and that architecture was the science of public health in its best and broadest sense. People would probably live to a great extent in the country, but he thought the appointment of a Minister of Public Health was an absolute necessity.

In the Section of Municipal and Parliamentary Hygiene the President, Dr. R. FARQUHARSON, M.P., delivered an address dealing with the general subject of municipal and Parliamentary hygiene. He thought that county councils had done their work well and that they should be allowed more freedom in framing by-laws regulating the health, comfort, convenience, and happiness of the people. He was of opinion that the expenses of county councillors should be paid. Resolutions in favour of the national registration of plumbers were then adopted, after which a paper was read by Mr. Fyfe, F.R.S. Edin., on Legal Stumbling-Blocks in the Housing Question.

In the afternoon, in splendid weather, an enjoyable garden party was held at Richmondhill, the residence of Lord Provost Fleming, and in the evening the official reception by the Lord Provost and Town Council took place in the Mitchell Hall and picture gallery at Marischal College, the apartments of the Students' Union being used as refreshment rooms. There was a very large and brilliant assemblage.

FRIDAY, AUGUST 3RD.

The annual meeting of the Association of Port Sanitary Authorities was held in the forenoon, when the office-bearers and council were elected. Reference was made to the recent epidemic of small-pox in Hull, and a resolution that the Local Government Board be asked to furnish forthwith to the officials of port sanitary authorities such information as it might receive as to the existence of infectious diseases, and that a deputation should wait on the President of the Local Government Board, was adopted. The tenth annual meeting of the registered plumbers in Aberdeenshire, Kincardineshire, and Banffshire was held in the evening, Professor M. HAY (Aberdeen), the President, being in the chair. The yearly report was satisfactory.

In the Section of Preventive Medicine a discussion, opened by Dr. E. W. HOPE (medical officer of health of Liverpool), took place on Municipal Laboratories as part of Health Organisations, and the following resolutions were adopted:—

That it is desirable that facilities should be acquired by sanitary authorities for bacteriological and other cognate work.

That it is desirable that the bacteriological diagnosis of disease should only be made by bacteriologists who are registered medical practitioners.

A discussion (commenced on the previous day) on the question of the notification of measles was continued and concluded. In connexion with the tuberculosis problem the following papers were read:—(1) Tuberculous Milk—Researches and Results, by Professor SHERIDAN DELÉPINE (Manchester), which was read in the absence of the writer; (2) The Dundee Sanatorium for Consumptives, by Dr. C. TEMPLEMAN (medical officer of health of Dundee); and (3) The Position of General Hospitals in Relation to the Sanatorium Treatment of Tuberculosis, by Dr. NOEL BARDSWELL (Surbiton). A brief discussion ensued, but no resolution was adopted. In a paper on Summer Diarrhœa, its Cause and Prevention, Dr. WILLIAM RUSSELL (Paisley) dwelt on the necessity of getting rid of all forms of putrefaction.

In the Section of Bacteriology and Comparative Pathology Dr. GEORGE DEAN (Jenner Institute of Preventive Medicine, London) gave a demonstration of Toxins and Antitoxins, illustrated by lantern slides, fully describing the methods of testing. The sera obtained by the use in immunising animals of living microbes, he said, were much less powerful than the antitoxic sera, but the method had been employed in such diseases as septicæmia, cholera, typhoid fever, and bubonic plague. Various theories as to the method of production of antitoxin in the animal body were touched on. Reference was made to some of the remarkable recent developments in the field of immunity, such as the production in the blood serum of animals treated with injections of rennet of a substance which neutralised the curdling of the rennet ferment on milk. Much of the work possessed at present only theoretical interest, but such investigations frequently paved the way for the discovery of practical methods of treatment and prevention of accident.—A paper by Dr. R. T. HEWLETT, (Jenner Institute of Preventive Medicine, London) was read in the absence of the writer, the subject being the Thermal Death-point of the Tubercle Bacillus. The general results of the writer's experiments were summed up as follows: Non-virulent laboratory cultures were destroyed by

an exposure to 60° C. for 10 minutes, while a temperature of 65° C. acting for 15 minutes destroyed the infective properties of tuberculous sputum. Tuberculous milk heated to 65° C. for 30 minutes lost its infective power, and tuberculous milk heated to from 65° to 68° C. for 20 minutes in the Allenbury pasteuriser likewise lost its infective power. In all probability pasteurisation, in which the milk is retained at a temperature of 65° C. for not less than 20 minutes, was efficient.—In the discussion Mr. B. BROWNING (medical officer of health of Weymouth) called attention to the fact that the laity were exposed to the danger of contracting tuberculous, enteric, and cancerous affections by receiving the sacramental wine in a cup, and he suggested to the clergy a modification of their ritual.—Papers were afterwards read upon the Serum Diagnosis of Typhoid Fever and the Bacillus Coli in Drinking Water.

In the Section of Chemistry and Meteorology the most interest was taken in a paper by Mr. JAMES HENDRICK, F.I.C. (Aberdeen), on the Question of Distillery Refuse, and in one by Dr. A. M. COWIE (Dufftown) on the Purification of Burnt Ale by the Biological Method.—Two papers on the Treatment of Sewage were also read, as was one by Dr. C. MUNRO HECTOR (Sheffield) and Dr. J. ROBERTSON (medical officer of health of Sheffield), entitled "The Estimation of the Germicidal Values of the Common Disinfectants."

In the Section of Architecture and Engineering Mr. R. MORHAM (city architect of Edinburgh) contributed a paper entitled "Suggestions on Fever Hospital Construction," in which he drew attention to the need of ample provision for fever nurses, and exhibited a block plan of the hospital now in course of erection for the city of Edinburgh.—Councillor COOPER (Aberdeen) read a paper on an Ideal Workman's Cottage, and a discussion followed on the difficulties of the problem of the housing of workmen in cities.—Papers were also read on House Drainage and on the Dangers to Public Health from Railway Carriages and Stations. The section recommended the Congress to call the attention of the various railway companies to the necessity of more efficient cleansing and the more sanitary construction of railway carriages, and also the conveniences at the smaller stations, having regard to the question of the possibility of infection to passengers.

In the Section of Municipal and Parliamentary Hygiene the Earl of ABERDEEN read a paper sent in by the Countess of ABERDEEN on Women as Members of Sanitary Authorities. At the suggestion of the section he promised to introduce in the House of Lords a Bill to amend the new Local Government Act for London so as to permit of women being elected, as before, as members of the local sanitary authority.—A paper by Dr. A. T. BEVERIDGE (Aberdeen) on Sanitation and Economics gave rise to a discussion on the advisability of working men becoming their own landlords.—Councillor DUNLOP (Glasgow) contributed a Plea for More Air Space in and Around Town Dwellings and a resolution was passed—

That this conference approves that the standard of air space for dwellers in cities and large towns be raised to 500 cubic feet for every adult and to 250 cubic feet for each child under 10 years of age.

The corporation of Aberdeen entertained the delegates to luncheon in the Music Hall, 1000 guests being present, and afterwards to a garden party in Duthie Park, where the company numbered 1200.

On Saturday, August 4th, several excursions were arranged for members of the Congress, the largest being to Balmoral, where by order of the Queen the Castle grounds were open to the visitors. The party which went to Finzean, near Banchory, were entertained to luncheon by Dr. R. Farquharson, M.P. for West Aberdeenshire.—On Sunday, August 5th, the delegates walked in procession to the West Parish Church, where the Rev. Dr. MARSHALL LANG (Principal of Aberdeen University) was preacher. There were also special services in St. Paul's (Episcopal) Church.

MONDAY, AUGUST 6TH.

Professor PERCY F. FRANKLAND, F.R.S., gave an interesting address on the subject of Recent Developments in the Purification of Sewage. The lecturer said that it was a matter for humiliation that in this country there was no proper organisation for carrying out experiments on an extensive scale. In this connexion he urged the establishment of an Imperial Board of Health.

At the annual meeting of sanitary inspectors Dr. A. T. GORDON BEVERIDGE (Aberdeen) was called to the chair.—Mr. PETER FYFE, F.R.S. Edin. (chief sanitary inspector, Glasgow), delivered the presidential address on Sanitary Inspectors and the Housing of the Poor.—Mr. GEORGE MACKAY (county sanitary inspector of Perth) read a paper on Improvement in Public Health in Scotland.—Miss MARY M. PATERSON, H.M. Inspector of Factories, then read a paper on Modern Workshops, dwelling on the necessity of cubic space and ventilation.

A conference of veterinary surgeons was thinly attended. Mr. W. WILLIAMS, F.R.C.V.S., principal of the New Veterinary College, Edinburgh, presided, and addressed the meeting on Certain Peculiarities, or rather Vagaries, in the Life-history of Microbes.

A conference of medical officers of health was held, Dr. J. C. MCVAIL (medical officer of health for Stirling and Dumbarton) presiding. The principal subject under discussion was the working of the English Vaccination Act.—Dr. FARQUHARSON, M.P., said he believed that the "conscientious objector" was a humbug and a manufactured product.

The Congress dinner was held in the evening.

TUESDAY, AUGUST 7TH.

To day, at an adjourned conference of veterinary surgeons, a paper was read by Mr. JAMES MCPHAIL (Edinburgh) on Pseudo-Tuberculosis.

The annual meeting of the Royal Institute of Public Health took place and the usual reports were adopted.

Dr. PATRICK MANSON, medical adviser to the Colonial Office, delivered an interesting address on Malaria: a Sanitary Problem, Lord ABERDEEN presiding. The members adjourned to the Pathological class-room, Marischal College, to view a number of slides illustrating the malarial parasite.

In the Section of Preventive Medicine, Dr. G. DEAN, who is in charge of the farm where the antitoxin is manufactured by the Jenner Institute of Preventive Medicine, delivered an address on the Seasonal Fluctuation in the Demand for Antitoxin. Other papers were read.

In the Section of Municipal and Parliamentary Hygiene, papers were read on Slum Property, the Necessity of Efficient Inspection of Meat and the Expediency of Erecting Compulsory Clearing Houses.

In the Section of Chemistry and Meteorology, a paper by Mr. R. GLEGG, B.Sc., and Mr. JAMES HENDRICK, B.Sc., was read on the subject of the Diurnal Variation in the Fat of Cow's Milk.

The proceedings closed with the general meeting of Congress, when various resolutions were adopted.

THE WAR IN SOUTH AFRICA.

THE IMPERIAL YEOMANRY HOSPITAL.

BY ALFRED D. FRIPP, M.S., F.R.C.S.

Since I wrote to you last I have been up to Mafeking to fetch Major Mullins who is now safely housed in one of our officers' wards here. He was so badly wounded in the backbone that we had to get a truck with sufficiently wide doors to admit the bedstead complete, and the guard's van was the only carriage that would meet the case. We also brought down Mr. Hands, the *Daily Mail* correspondent, who, too, had been wounded in the relief at the same time, so that there is not a seriously sick or wounded man now left in Mafeking. I had been suffering from a poisoned finger and the rest from work enabled it to get quite well. At the same time the trip afforded a most interesting experience. The "dug-outs" or "bomb-proof shelters" have most of them disappeared already, for their roofs were generally made of railway metals which had to be restored to their proper places before the line could be reopened. Fuel is still very scarce up there, the locomotives having to depend on wood of which they draw a huge truckful after them. Of food there is plenty and of danger there is none, though there was indeed a slight skirmish only seven miles out of Mafeking while I was there, and the passengers by the train after ours saw a couple of shells bursting not long before they reached Mafeking. There seem to be various small commandoes of the enemy moving about even in parts of the country that have for many weeks been considered disarmed; there is one such between us and Kimberley,

and another between Norval's Pont and Naauwpoort, a slight skirmish taking place the other day at the former place. But in all other respects little change has as yet come over Mafeking since it was relieved.

It is most interesting to be taken over the forts and trenches by one of those who was responsible for their making and who knows the why and wherefore of each move and of each fight. The "Brickfields" in particular might be described as a chessboard on which a most clever and spirited game had been played for several months for great stakes. There, as I daresay you know, our trenches were pushed up to within 60 yards of the Boer trenches before these were evacuated, and then our men sapped on until the two trenches joined and they could pass all the way under cover from one of our forts to one made by the Boers. This they found was deserted, but luckily before occupying it they stumbled on an electric fuse wire and cut it, and then found 250 lbs. of dynamite which was meant for their destruction. This was 1350 yards from the market square and 800 yards from the main Boer position. They were hard up in the town for some wire of this sort, so they picked up the cut end and began to haul it in before the Boers, who were ineffectually pressing the button which made the connexion which was to have blown up the fort, discovered what was happening. A tug-of-war ensued and our men got 750 yards and the Boers only 50.

"Trophies" and mementoes of the siege of all sorts are in great demand both at Mafeking itself and also down country. Siege stamps, paper money, shells, and bullets occupy the most prominent place in many people's minds, and realise most extraordinarily high prices; but Professor Chiene, who was visiting us not long ago, is the possessor of one of the most interesting mementoes in the shape of the concertina whereby, in conjunction with the noise made by a native dancing on a sheet of corrugated iron, the Boers were tempted to put up their heads when only separated from our sharpshooters by the 60 yards already mentioned. Many Boers paid for their curiosity with their lives, for the moment anything showed above the sandbags it got a bullet through it; even a cartridge case, which is only two and a quarter inches by less than half an inch, left by chance on the top of the sandbags got two bullets put through it. I dare say you know that there are some field-glasses made on such an arrangement of angles and prisms that by their aid a man in a trench can spy over the top without exposing his head. I saw one such glass which had had a Mauser bullet bang through its lens and the bullet also went through the hat of the person who was using it.

The Stadt, or native compound, is another very interesting part of the besieged area to visit. It stands separated from the town by a small river bed. The force which occupied this quarter of the outer and inner circles of forts was usually composed almost entirely of natives. Twice at least this native Stadt was the object of hot attack. On the first occasion the Boers broke through the outer circle of forts which surround the town at a radius of from about half a mile to one mile, but were repulsed at the inner forts which closely encircle the town. On the second occasion (May 12th), headed by Eloff, the Boers, as you know, got right into the Stadt and set on fire many of the native huts. They pushed on and got almost to the railway station. Reinforcements of white troops then got round behind them and cut off their retreat. Here many of them surrendered towards nightfall, but of those who tried to retrace their steps through the Stadt, it is said that some were thrown by the natives into the burning houses.

Both at Mafeking and at Ladysmith the besieged forces seem to have placed a very modest estimate upon the splendid services which they themselves had yielded. An officer who was in Ladysmith said to me the other day: "When the relief force came in we were surprised to find that we were heroes—we thought we had all been doing very badly." One whom I saw at Mafeking who on the testimony of his colleagues seemed to have taken a most active part in the fighting and, indeed, in the most dangerous parts of it, said: "Our success in keeping the enemy out is due not so much to what we did as to what the enemy failed to do."

Both the convent and the hospital were, as you know, severely damaged by shell fire. The former, which is the only two-storeyed building in the town and therefore afforded a tempting target from the Boer lines, might almost be described as a ruin, but the latter is the one building in the town which has already been repaired.

Throughout the siege they seem to have been remarkably free from sickness, despite the fact that Mafeking is as innocent as any other town in South Africa of any attempt at sanitation.

I am glad to say that sickness among the staff here has materially diminished of late. Only 21 of our orderlies are "in hospital" and they are all doing well, and so are the two medical men who are convalescent from enteric fever and a couple of sisters who are off duty through slight ailments. This most satisfactory abatement seems to be general throughout the country. The epidemic of enteric fever continues to decrease rapidly.

Colonel A. T. Sloggett, R.A.M.C., who is just back from Pretoria, whither he had to go to make arrangements for the new advanced branch of the Yeomanry Hospital, the first instalment of which is due at Cape Town to-morrow, says that there are only 400 sick and wounded in that city and only 1600 in Bloemfontein, instead of the 5000 who were there when I was there six weeks ago. He says that there are two whole general hospitals now in Kroonstad besides the Glasgow Hospital of 300 beds; but there, as at Kimberley, where I visited the hospitals on my way to Mafeking, and everywhere else that the hospital trains ply to, the report is extremely favourable, and there are vacant beds everywhere now. The difficulty of transport, however, continues. Between Kroonstad and Johannesburg it is even greater than it was, owing of course to the depredations of Christian de Wet.

We have taken in nearly 250 patients this week, including one trainload from Wynberg, half sick and half wounded and one trainload of convalescents from Pretoria, and about, 50 Yeomanry, including a batch of the Warwicks and a batch from Kimberley.

From talking to Boer prisoners it is evident that their leaders are still trying to buoy them up with the most gross misrepresentations. One said that his commando had been told that 6,000,000 Russians had been landed in Cape Town and that Cronje and all of his men had escaped from St. Helena and were invading the Cape. They say that the Boers have changed the name they apply to our troops from "rooineks" to "locusts."

On my way through Kimberley the other day I ordered and brought down with me on the return journey a marble cross for the head of the late Dr. R. T. FitzHugh's grave. By-the-bye, about a week ago the Coadjutor Bishop of Cape Town paid us a 24 hours' visit for the purpose firstly of dedicating our burial-ground, and secondly, of holding a confirmation service for which some eight or nine candidates had been prepared by our clergyman, Mr. Blackbourne.

We have experienced a day or two of really horrible weather here lately. Tremendously high winds, very cold indeed and bearing along clouds of dust and even of shingle which felt at times almost like a flight of small shot. Several of the larger tents, including the sisters' dining tent (poor souls!), were blown down, and it has been impossible yet to put them up again owing to the continued high wind. None of the tortoise- or bell-tents have been blown down, nor of course, were the huts damaged, but everything and everybody have been covered with dust.

Deelfontein, July 16th.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool Sanitary District.—Dr. E. W. Hope is looking anxiously forward to the results of the 1901 Census to ascertain the precise position of Liverpool with regard to her several death- and disease-rates. At the last census the experience of Liverpool was peculiarly unfortunate in that the discrepancy between the actual and estimated population was no less than 100,000. Small wonder that under these circumstances the medical officer of health pleads for a quinquennial census. For 1899 the estimated population of the city was 668,645, the birth-rate being 33·6 and the death-rate 24·3 per 1000. The highest district birth-rate was 44·1 and the lowest 20·1 per 1000, while as regards the district death-rate the highest was 38·7 and the lowest 10·1 per 1000. In connexion with the deaths it is an interesting point, and one

worthy of study, that the deaths which take place in workhouses and hospitals are greater in Liverpool in relation to population than is the case in any other city of England. The table below gives the rates for the four largest towns.

	1895.	1896.	1897.	1898.	1899.	Average.
Birmingham ...	16·8	14·9	14·0	15·3	16·1	15 4
Leeds...	10·9	11·9	10·8	11·8	12·4	11·6
Manchester ...	19·2	19·7	20·0	19·0	19·7	19·5
Liverpool... ...	20·7	23·8	23·1	24·7	25·3	23·5

Small-pox was introduced into Liverpool on six occasions during 1899, but, owing to the precautions taken the disease failed to spread. Of typhus fever 70 cases were brought to the notice of the sanitary authority, and of these 13 died. Dr. Hope furnishes an interesting diagram in his report showing how the disease spreads, and the importance of keeping those who have been exposed to infection under rigid observation. In discussing measles Dr. Hope deplores the fact that the deaths from this disease show no evidence of decline, and he compares the behaviour of this disease with that of such diseases as typhus fever and scarlet fever, to both of which isolation has been applied. Dr. Hope is apparently of opinion that isolation would tend to materially diminish the prevalence both of measles and whooping-cough, and in respect of the latter disease he furnishes a table showing in what manner the disease may be considered as spreading. Under the heading of Alcoholism the effect of drink upon the survival of children born of alcoholic mothers is well brought out, and it is related that out of 600 children born of inebriate mothers no less than 335 died before their second birthday. The female sanitary inspectors are making their influence felt in Liverpool, and during 1899 three additional officers were permanently added to the staff. These officers do excellent work in the direction of educating the public in some of the principles of preventive medicine. Open spaces are being provided in Liverpool by the conversion of old burial-grounds into gardens, and Dr. Hope furnishes photographs showing (*a*) converted churchyards, and (*b*) churchyards closed against further interment. As an instance of the immense overcrowding of bodies in a given grave he introduces the photograph of a gravestone completely covered with separate inscriptions indicating the persons who have been buried beneath the stone in question. Considerable space is devoted in the report before us to the subject of preservatives and colouring matter in food. It is a very interesting and important fact that the addition of such preservatives as formalin or boric acid to milk is a relatively uncommon practice in Liverpool, and, as Dr. Hope points out, it is clear that their use is not urgently called for provided proper cleanliness and cooling are practised. Dr. Hope also refers to the experiments carried out by Dr. H. E. Annett at Liverpool upon kittens, in which the evidence pointed strongly in the direction of relatively small amounts being detrimental to these animals. The tanyards of Liverpool proved during 1899 to be invaded by anthrax, and four deaths from this disease occurred during the year. The bacillus of the disease was found in the gloves used by the workmen and also in the vats used for macerating the hides. In connexion with the summer diarrhœa of infants the milk with which certain of them were being fed had been examined bacteriologically. Many putrefactive organisms were detected, and among them the bacillus enteritidis sporogenes. Some interesting observations with regard to the presence of the tubercle bacillus in milk were made by Professor R. W. Boyce. In railway-borne milk tubercle was found in 8·1 per cent. of the samples, but in the town milk only 0·6 per cent. was found to be tuberculous. Several specimens of condensed milk were not sterile, organisms being found therein; so, too, bacteria were detected in samples of "sterilised milk." No pathogenic organisms were detected in the specimens of jam examined, and many samples were quite sterile. Professor Boyce evidently views the practice of adding preservatives to jam as likely to lessen its digestibility. Certain tinned meats contained numerous organisms, but apparently none of the shellfish examined on this occasion contained disease-producing organisms. Samples of drinking-water were examined at frequent intervals, but the average number of bacteria was always below Koch's standard of 100 per cubic centimetre. The corporation of Liverpool is steadily demolishing some of the worst slum property, which has been for years past identified with disease and misery, and with death-rates of between 40 to 50 per 1000; in a word, the localities where, since statistics have been collected, disease has been in a sense endemic. Of some of this miserable property and of its pale-faced inhabitants Dr. Hope supplies photographs, while by way of contrast he adds a picture of some of the buildings erected by the corporation. Whether or not the occupants of the slums destroyed find a home in the model dwellings there must be at least some advantage in sweeping the worst slums out of existence.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 33 of the largest English towns 6889 births and 4564 deaths were registered during the week ending August 4th. The annual rate of mortality in these towns, which had increased from 14·5 to 19·4 per 1000 in the four preceding weeks, further rose to 20·5 last week. In London the rate was 20·1 per 1000, while it averaged 20·8 in the 32 provincial towns. The lowest death-rates in these towns were 8·0 in Burnley, 9·4 in Cardiff, 11·1 in Wolverhampton, and 11·4 in Halifax; the highest rates were 26·2 in West Ham, 30·0 in Salford, 33·5 in Sheffield, and 34·6 in Liverpool. The 4564 deaths in these towns included 1329 which were referred to the principal zymotic diseases, against 427, 555, and 944 in the two preceding weeks; of these, 1040 resulted from diarrhœa, 88 from whooping-cough, 79 from measles, 70 from diphtheria, 26 from scarlet fever, 25 from "fever" (principally enteric), and one from small-pox. The lowest death-rates from these diseases were recorded in Cardiff, Oldham, Burnley, Halifax, and Gateshead; and the highest rates in West Ham, Liverpool, Salford, Preston, and Sheffield. The greatest mortality from measles occurred in Brighton, Derby, Huddersfield, Leeds, and Sunderland; from whooping-cough in West Ham; from "fever" in Portsmouth; and from diarrhœa in West Ham, Liverpool, Salford, Preston, and Sheffield. The mortality from scarlet fever showed no marked excess in any of the large towns. The 70 deaths from diphtheria included 24 in London, eight in Leeds, eight in Sheffield, seven in West Ham, and seven in Leicester. One fatal case of small-pox was registered in Blackburn, but not one in any other of the 33 large towns. There were seven cases of small-pox under treatment in the Metropolitan Asylums Hospitals on Saturday last, August 4th, against 17, 14, and 11 at the end of the three preceding weeks; no new case was admitted during the week, against four, one, and three in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1827, against 1877 and 1859 on the two preceding Saturdays; 156 new cases were admitted during the week, against 208, 222, and 207 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 140 to 196 in the four preceding weeks, declined again last week to 136, and were 43 below the corrected average. The causes of 53, or 1·2 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Nottingham, Bolton, Newcastle, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Huddersfield, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·0 and 17·5 in the two preceding weeks, further declined to 17·2 per 1000 during the week ending August 4th, and was 3·3 per 1000 below the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 13·3 in Dundee and 13·5 in Perth to 19·3 in Paisley and 19·5 in Glasgow. The 533 deaths in these towns included 60 which were referred to diarrhœa, 19 to measles, 12 to whooping-cough, 11 to "fever," five to diphtheria, two to small-pox, and not one to scarlet fever. In all 109 deaths resulted from these principal zymotic diseases, against 102 and 87 in the two preceding weeks. These 109 deaths were equal to an annual rate of 3·9 per 1000, which was 2·1 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 38 and 36 in the two preceding weeks, further increased last week to 60, of which 37 occurred in Glasgow,

seven in Paisley, five in Dundee, three in Edinburgh, and three in Aberdeen. The deaths from measles, which had risen from 17 to 24 in the three preceding weeks, declined again to 19 last week, and included 14 in Glasgow and four in Edinburgh. The fatal cases of whooping-cough, which had been 22 and nine in the two preceding weeks, rose again last week to 12, of which nine were registered in Glasgow and two in Greenock. The deaths referred to different forms of "fever," which had been 11 and six in the two preceding weeks, rose again to 11 last week and included six in Glasgow and four in Edinburgh. The fatal cases of diphtheria, which had been four, six, and one in the three preceding weeks, rose again last week to five. The deaths from small-pox, which had been two in each of the two preceding weeks, were again two last week, and were both registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 80 and 67 in the two preceding weeks, increased again to 73 last week, and were 21 in excess of the number in the corresponding period of last year. The causes of 30, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·4 and 18·3 per 1000 in the two preceding weeks, rose again to 24·0 during the week ending August 4th. During the past four weeks the death-rate in the city has averaged 21·0 per 1000, the rate during the same period being 17·9 in London and 17·1 in Edinburgh. The 161 deaths belonging to Dublin registered during the week under notice were 38 in excess of the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against eight, 13, and five in the three preceding weeks; of these, nine resulted from diarrhœa, three from whooping-cough, two from "fever," and not one either from small-pox, measles, scarlet fever, or diphtheria. These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 5·7 in London and 2·2 in Edinburgh. The deaths referred to diarrhœa, which had been four in each of the two preceding weeks, increased to nine last week. The 161 deaths in Dublin last week included 33 of infants under one year of age and 43 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a considerable excess over the numbers recorded in the preceding week. Eight inquest cases and four deaths from violence were registered; and 59, or more than a third, of the deaths occurred in public institutions. The causes of six, or nearly 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: Hugh P. Turnbull to the *Duke of Wellington*; Edward T. P. Eames to assist Board of Medical Officers in examination of candidates for commissions in Royal Marines; and Malcolm Cameron to the *Northampton* for *Cleopatra*.

ROYAL HORSE GUARDS.

Surgeon-Captain Hugh Rayner to be Surgeon-Major, in succession to Surgeon-Lieutenant-Colonel J. S. Forrester, deceased.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants to be Captains: Stevenson Lyle Cummins, Joseph McArdle, Charles Hensley Hopkins, Lewis Julius Christopher Hearn, Peter McKessack, John McDonald McCarthy, Ernest Brodribb, John Poe, Henry Lawrence Weekes Norrington, Hamilton George Frampton Stallard, Robert Dalkeith Jephson, and Arthur Winniett Nunn Bowen. Lieutenant-Colonel Abraham Walker Browne is placed on temporary half-pay on account of ill-health.

VOLUNTEER CORPS.

Royal Engineers: 2nd West Riding of Yorkshire (Leeds): Surgeon-Lieutenant H. Waite to be Surgeon-Captain. *Rifle:* 5th Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant J. R. I. Raywood to be Surgeon-Captain. 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant G. Black to be Surgeon-Captain and to remain supernumerary. 3rd (Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment: Captain Charles Henry Newby resigns his commission and is appointed Surgeon-Lieutenant. 1st Volunteer Battalion Princess Charlotte of Wales's (Royal Berkshire Regiment): Surgeon-Captain A. G. Paterson resigns his commission. 2nd London: Surgeon-Captain W. A. Bond resigns his commission. 15th Middlesex: Surgeon-Lieutenant James Godding resigns his commission and is appointed Lieutenant. 19th Middlesex: John James Rickard Macleod to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies: Surgeon-Major W. Coates to be Surgeon-Lieutenant-Colonel on increase of establishment and to command under paragraph 55A Volunteer Regulations. Surgeon-Captain J. J. K. Fairclough to be Surgeon-Major.

TRANSVAAL WAR NOTES.

It has been decided to send out at once to South Africa a large reinforcement of trained men of the Royal Army Medical Corps.

Major J. Meek, R.A.M.C., has been appointed Principal Medical Officer of the American hospital ship *Maine*.

Major Raymond, R.A.M.C., Captain Mason, R.A.M.C., Lieutenant-Colonel Barker, R.A.M.C., Captain Butler, R.A.M.C., Captain Stalkartt, R.A.M.C., and Civil Surgeon Parker are reported on their way home from South Africa invalided.

THE CRISIS IN CHINA.

A third brigade, to consist of the 4th and 20th Punjabis, the 6th Bengalis, and one regiment of Hyderabad Infantry is to proceed to China. The transport *Canning*, with the 4th Battalion of the 1st Goorkhas, the 66th Native Field Hospital, details, and supply column, and the transport *Nation*, with ordnance park, transport mules, the 39th Native Field Hospital, native general hospital, and special service details, has arrived at Hong-Kong.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The fortieth class for the instruction of medical officers in the subjects of the proficiency examination will be held at the headquarters of the Prince of Wales's Own, 12th Middlesex (Civil Service) Volunteer Rifles, Somerset House, Strand, W.C., by permission of Lieutenant-Colonel H. B. H. Tytheridge, commanding that regiment, and will last five days, commencing on Monday, Sept. 24th, at 2.30 P.M. precisely, and concluding on Friday, Sept. 28th, at 5.30 P.M. The instruction will include all the subjects of the examination, also the duties of medical officers generally in camps, quarters, bivouacs, with brigade bearer-companies and other units, on the line of march and elsewhere. Practical instruction in bearer company drill will form an important part of the work of the class. Officers who are unable to attend this class can obtain instruction by correspondence. These classes will be under the instruction of Surgeon-Captain E. M. Callender, 40, Connaught-square, Hyde-park, London, W., to whom all officers should apply who intend to join either class or who wish for further information, at the same time stating their rank and corps.

Correspondence.

"Audi alteram partem."

"PROFESSOR LUSTIG'S PLAGUE SERUM."

To the Editors of THE LANCET.

SIRS,—Your special Indian correspondent, fully appreciating the importance of the subject, made a point of reporting periodically to your readers on the progress of the experiments which were initiated with Professor Lustig's curative plague serum in 1898 by the municipality of Bombay. Evidently possessed by the conviction that he could advance best the cause of humanity and science from the comfortable standpoint of absolute negation he has from the beginning been eager to assert that the results obtained were utterly fallacious and wholly due to the selection of the cases which

was practised at first. He, moreover, for reasons religiously kept to himself did not approve of the method of the manufacture of the serum.

Such condemnatory verdict, pronounced in a leading medical journal, did not necessarily tend to lessen the already existing difficulties in carrying on the experiments, for the successful termination of which, however, the authorities and the public were equally desirous. Fortunately his arguments betrayed a lack of personal information and an overflow of imagination surprising even in a special Indian correspondent, and they failed to convince the responsible persons who were on the spot and knew the real facts. The experiments, therefore, were allowed to proceed on the lines laid down by the experimenters in spite of his scathing criticism. Thus it happened that in April last I was in the position, as one of the medical officers entrusted by the municipality for some time past with the manufacture of the serum, to lay the following statistical details based on official records before a special meeting of the Bombay Medical Union:—1. From March 13th, 1898, till May, 1899, 403 "selected" patients were treated with the serum at the Arthur-road Hospital and had a recovery-rate of 33·2 per cent., whereas the 1190 patients who were excluded from the serum treatment and treated by ordinary methods had a recovery-rate of 19·5 per cent. This rate of the excluded patients was found to be identical with the recovery-rate of the other large plague hospitals, and gives, therefore, the proof that the increase on the serum side was real and not due to the selection. That is further corroborated by the fact that the total recovery-rate at the Arthur-road Hospital was 4·5 per cent. higher than in other hospitals. 2. From April, 1899, till April, 1900, 361 patients were treated with the serum at the same hospital and had a recovery-rate of 33·8 per cent. These patients were *not* selected but taken alternately as they were admitted, an equal number remaining as controls under the ordinary treatment. The controls had a recovery-rate of 21·3 per cent., this rate being again identical with that of the other hospitals. The total recovery-rate of the Arthur-road Hospital was consequently 6 per cent. higher than that of the other hospitals. On the strength of these statistics and various other evidence I felt myself entitled to conclude: (*a*) that the experimental stage of the serum treatment was over; (*b*) that the curative properties of the serum had been established beyond reasonable doubt; (*c*) that they were represented at present by the improvement of 12·5 per cent. obtained in the patients taken alternatively for treatment; (*d*) that they were satisfactory in themselves; and (*e*) that they were certain to be improved upon with the increasing experience in the manufacture and application of the serum.

The medical practitioners attending the meeting—foremost amongst whom was the President of the Bombay Medical Union, Sir Balchandra Krishna, whose distinguished services in combating the plague won him the knighthood—certainly the best judges of the facts placed before them, accepted the statistics and conclusions as correct, unanimously considering "that the serum was the only curative remedy against plague of some potency at present known to the scientific world, the cures effected by it being at present 12 per cent. more than cures with the ordinary treatment," and passed unanimously the following resolution to be brought before the Corporation of Bombay for favourable consideration:

1. That this meeting of the local medical profession is of opinion that the treatment of plague with Professor Lustig's curative serum has given encouraging results, even under the unfavourable circumstances of hospital treatment, and that its use should be extended for the benefit of patients allowed to be treated at their houses by private practitioners. 2. That greater facilities than those given hitherto should be afforded to private practitioners in order to encourage the use of the serum in private practice. 3. That the President be requested to communicate this resolution to the President of the Corporation and the Municipal Commissioner, and to enter into such correspondence with them on the subject as seems to him necessary.

This resolution was considered by the corporation at their meeting of May 28th last, and forwarded to the Municipal Commissioner for favour of remarks. The Commissioner thereupon took immediate steps to comply with the contents of the resolution and rules for the use of the serum in private practice were framed under the supervision of Lieutenant-Colonel J. S. Wilkins, I.M.S., D.S.O., the Special Medical Officer, Plague Operations, appointed by Government, who as the result of his observations in the plague hospitals under his charge has become a keen supporter of the serum treatment.

Considering that the views entertained by your correspondent had thus been proved to be at variance with those of the responsible authorities in Bombay and with the facts, one might rightly have expected that he would have hastened to correct the wrong impression he had forced upon your readers and not have hesitated to admit the errors he had fallen into. But instead of reporting on the gratifying and promising conclusion of the experiments with Professor Lustig's serum, as would have been his duty, your correspondent reiterates *ad nauseam* his flimsy arguments in your issue of June 2nd, p. 1608, discussing the paper I read before the meeting of the Bombay Medical Union in the confused, illogical, and contradictory style quite his own—at least whenever he has occasion to write on Professor Lustig's serum treatment of plague. By an ingenious juggling once more with the bugbear of the selection of cases and by dismembering and misquoting my statements he almost succeeds in conveying the idea that the 12 per cent. claimed as improvement for the treatment have also been obtained in selected cases. And not content with this achievement he gives the last touch to the performance by doubting my figures and by deliberately insinuating that the improvement of 12 per cent. as shown by me is not real and has been arrived at by an ambiguous arrangement of figures.

I do not intend to disprove in any way your correspondent's assertions, as in doing so I would be compelled to violate the etiquette so strictly observed in controversies—viz., never to call in question the *bona fides* of arguments or statements. But what I would permit myself to say here is that anyone who has read my paper on Lustig's serum—and I trust that you, Sirs, on receipt of this will take the opportunity of reading it—and who has also read the comments of your correspondent upon it in your issue of June 2nd, must arrive at the conclusion that he either did not read my paper or did not understand it or did not want to understand it. Little flattering as the first two alternatives might be for a special correspondent and an English medical man, they are no doubt to be preferred to the third. It is much to be regretted that in a matter of great public and scientific interest which not only concerns the poor inhabitants of India, but may also at any moment concern our own families and fellow countrymen in Europe, one of the foremost medical papers of Great Britain should have to depend for its information on a correspondent who is unable to give an unbiased statement of the facts, and who, without possessing the requisite knowledge, criticises unfairly the facts and figures brought forward to show the results of the treatment of plague cases with Professor Lustig's serum.

I am, Sirs, yours faithfully,

A. MAYR, M.D.

Municipal Laboratory, Parel, Bombay, July 6th, 1900.

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to an article on Professor Lustig's serum which appeared in THE LANCET of June 2nd, written by your Special Correspondent in India. As one other amongst the advocates of this serum than Dr. Mayr I must call your attention to the inaccuracies which this article contains. Dr. Mayr himself is answering the various errors of your correspondent and I fully concur in what he states. As far as I am concerned in the matter I may say that as special medical officer in charge of all the plague hospitals in Bombay I have had full opportunity of seeing for myself the value of the experiments carried on at the Arthur-road Hospital with this serum and cannot understand how your correspondent could mislead you and your readers in the way he has done. As Dr. Mayr has gone into the subject fully I need not occupy any more of your space except to say that the first experiments up to May, 1899, were carried on with selected cases; since May, 1899, and up to the present time we have had every alternate case of plague admitted to this hospital treated with the serum and have nearly reached 500 on either side. On a visit of Professor Schotteleus of Freibourg University last cold weather to study the plague in Bombay he was so much interested in the results of the serum treatment that on his return to Europe he very kindly obtained for us some curative serum from the Pasteur Institute. When this arrives I propose to use it on every alternate case with Lustig's serum—i.e., one case treated with Roux's and one with Lustig's serum.

I am, Sirs, yours faithfully,

JAMES S. WILKINS, Lieut.-Col., I.M.S.,
Special Medical Officer, Plague Hospitals, Bombay.

Lansdowne House, Bombay, July 6th.

"THE MEDICAL STAFF AND THE MANAGEMENT OF THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE."

To the Editors of THE LANCET.

SIRS,—We have seen with much surprise that the special general meeting of governors and subscribers "to consider and determine the following questions—that is to say (1) whether the demand of the medical and surgical staff for direct representation upon the board should be granted; and (2) whether it is desirable to hold a further inquiry into the condition of the hospital" has been fixed by the board of management for Saturday, August 11th. That date has been selected, according to the secretary-director, as representing "the earliest day permitted by the rules." Unfortunately, it falls in the very heart of the holiday season, when it will be impossible for any large proportion of the governors to attend the meeting. The great majority of the medical staff will also be away from town. Under these circumstances, feeling that a full and fair consideration of the questions is impossible at this time, we have requested the board of management to postpone the meeting till the end of October when an adequate attendance of governors can be secured, and have intimated to him that it is not possible for the medical staff to be represented at the meeting on August 11th, or to take any part in it. We would point out that any decision arrived at on Saturday next cannot be regarded as final and that we shall be ready, at a meeting summoned at an appropriate time, to place fully before the governors our view of the questions at issue.

We cannot venture to trespass on your space to the extent which would be necessary to point out all the statements in the letter of the secretary-manager in the *Times* of August 3rd which are calculated to mislead; but it appears to us distinctly necessary to object to what is represented as the "clear issue," and also to the apparent intention to limit the scope of the inquiry to the present condition of the hospital. What is needed is as described by us in our letter of July 27th,[1] "a full and searching inquiry into the constitution and management of the hospital, to be carried out by an independent and, at the same time, competent body."

We are, Sirs, your obedient servants,

J. HUGHLINGS JACKSON, M.D. St. And., F.R.C.P. Lond., F.R.S.,
THOMAS BUZZARD, M.D., F.R.C.P. Lond., Consulting Physicians to the Hospital.

(The names of absent members have been added by authority.)

August 6th, 1900.

"ADDISON'S DISEASE AND LEUCODERMA."

To the Editors of THE LANCET.

SIRS,—With reference to the interesting and valuable remarks of Sir Samuel Wilks on Addison's Disease and Leucoderma, together with Sir W. T. Gairdner's letter thereon, may I be permitted to refer to a case bearing on the point under discussion, mentioned by Heller in his recent paper on Morbus Addisonii.[1] This writer states he has seen one case of Addison's disease with symmetrical leucodermic areas, but he gives no details.

I am, Sirs, yours faithfully,

GEORGE PERNET.

Upper Gloucester-place, Dorset-square, N.W., August 6th, 1900.

[1] THE LANCET, August 4th, 1900, p. 351.

THE COVENTRY PROVIDENT DISPENSARY.

To the Editors of THE LANCET.

SIRS,—At the general meeting of the British Medical Association no doubt many of the members present were surprised at the attitude of Dr. Saundby in supporting the medical men holding appointments in the Coventry Provident Dispensary and condemning any attack upon that institution. It is plain that an ex-president of Council in supporting such an institution has not made himself conversant with the facts of the case, seeing that it has been condemned by the ethical branch of the British Medical Association, THE LANCET, the *British Medical Journal*, and the *General Practitioner*, and was condemned also at the annual meetings at Edinburgh and Portsmouth, and that the institution is entirely without a wage-limit, and accepts members without any regard to their social position. This dispensary is one of glaring abuse and has been severely criticised by various committees of the Association; in addition, it has been closely investigated by a Special Commissioner of THE LANCET, who represented it as being one of the most abused institutions in the kingdom. Under these circumstances the Association will stultify itself if it takes no action in the matter, after the strong expression of opinion at the annual meetings. The profession in Coventry would suggest that the Council should appoint a special delegate (not a Birmingham consultant) to visit Coventry and report upon the whole question in dispute.

I am, Sirs, yours faithfully,

EDWARD PHILLIPS.

Coventry, August 7th, 1900.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Small-pox and Raw Cotton.

AN outbreak of small-pox in the urban district of Littleborough is giving some anxiety. It seems that all the persons who were attacked were employed in the card-room of one of the mills. Dr. G. C. Pitcairn, the medical officer of health of Littleborough, suggested that the manipulation of infected raw cotton started the four first cases. Precautionary measures were strictly enforced and isolated cottages secured as soon as possible for the convalescent cases until thorough disinfection could be carried out. The matter was discussed at the last meeting of the Lancashire County Council when some members considered that the suggestion as to its origin was based on surmise, and that the matter should have been more fully investigated before being printed in an important report, as it was "a most serious thing for Lancashire." Of course it is, and hence it is all the more necessary that it should be thoroughly investigated. That small-pox should occasionally be conveyed in cotton bales does not seem improbable, but it must occur so rarely that no great scare need arise. On the face of it the history of the cases certainly points to a common source of infection.

The Port Sanitary Authority.

At the meeting of the Manchester City Council on August 1st it was agreed to request the Local Government Board "to make an order constituting a permanent port sanitary authority out of all the councils abutting on the port, giving them adequate representation and desiring them to contribute proportionately to the expenses of the authority." So far the expenses have been borne by Manchester, Salford, and Stretford, but other towns,

[1] Encyklopädie der Haut- und Geschlechts-Krankheiten, p. 11. Edited by Lesser. Leipsic, 1900.

Ellesmere Port, Runcorn, and Warrington, for instance, have important commercial interests on the Ship Canal and ought to pay their share. So far they have not agreed as to the proportion they should bear. The Local Government Board are, therefore, to be asked to formulate an equitable scheme "as a mutual reciprocal arrangement seemed impossible."

Pollution of Gore Brook.

One of the most attractive and picturesque open spaces possessed by Manchester, Birch Park—or Birch Fields, as it used to be called—is traversed by a flowing brook which ought to add to the scene a beauty of its own. But the stream is black and its odour abominable, and Mr. McDougal, as alderman of the Rusholme ward of the city of Manchester, has again brought the matter before the Joint Rivers Committee. He states that although the city council have taken temporary measures to deodorise the water it is still "a source of danger and annoyance to residents in the neighbourhood and others who visit Birch Park." It was pointed out 12 months ago by a deputation representing the inhabitants of Rusholme that the stream was polluted almost from its source by a part of the sewage of Audenshaw, Droylsden, and Gorton. Promises of amendment were made by the various authorities, but only to be broken, for practically no purification has taken place. The usual excuses are made—more time required, plant not completed, &c. In the meantime the sewage flows on, and being heavily charged with a chemical precipitant all the settlement takes place in the stream itself. One of the committee said that he had seen upwards of 50 children wading in this open sewer, and "he could hardly think that the Parks Committee of the Manchester Corporation had done their duty in the matter." Proceedings are to be taken against two of the authorities, and in the meantime this unsavoury tributary of the Ship Canal flows on unchecked till its foulness is lost in the still greater foulness of the canal itself.

The Blackburn Guardians and Vaccination.

At the meeting of the Blackburn board of guardians on August 4th it was reported that Dr. James Wheatley, medical officer of health for the borough, had written saying that he thought it advisable, owing to the prevalence of small-pox in the town, that all the inmates of the workhouse should be revaccinated. It was decided to take no notice of the letter but to stop visiting at the workhouse. This decision means apparently that the guardians deny the inmates of the workhouse the protection from small-pox afforded by revaccination. Are paupers not entitled to such protection if they wish to have it? Shut off very much from the outer world and more ignorant possibly than the guardians, they may know but little of the danger of their contracting small-pox owing to its prevalence in the town, but in practically denying them protection the guardians take upon themselves the responsibility of any cases of small-pox that may occur among them.

The Medical Officership of Crewe.

The Town Council of Crewe and the Local Government Board have been in correspondence as to the stipend of the medical officer of the borough. Dr. Alfred Greenwood of Stockport has been appointed as successor to Dr. Meredith Young at a commencing salary of £300. The Local Government Board, no doubt considering that this was too little to pay to a gentleman who was to give his whole time to the service of such a populous and important town, suggested that his salary should not be less than £500. But—showing how old sins bring their Nemesis—the Council were able to retort that in the case of a former medical officer the Board had sanctioned £300 as the salary. The Board, therefore, finally stated that, "while they would have preferred" a salary of £500 a year, they would be ready to sanction an appointment at £300 a year, "on the understanding that, while giving his whole time to the council in other respects, he should be at liberty to supplement his income by acting as a consultant in cases of infectious disease if invited to do so by any other medical practitioner, by performing analyses and other laboratory work, and by receiving qualified medical men as pupils for instruction in sanitary science, and in other public work of a similar character not involving the ordinary work of a general practitioner." This is a remarkable compromise on the part of the Local Government Board.

August 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Graduation Ceremonial at Edinburgh University.

THE summer graduation ceremonial of Edinburgh University was held in the McEwan Hall on July 28th. As usual the majority of the degrees conferred were in the Faculty of Medicine. Mr. John Philip Wood, W.S., professor of conveyancing in Edinburgh University, was the only recipient of an honorary degree—that of Doctor of Laws. The degree of Doctor of Medicine was conferred on 53 gentlemen. Gold medals were awarded to three of these—viz., Walter William Chipman (B.A.), Canada, M.B., C.M., 1895; David James Galloway, Scotland, M.B., C.M., 1884 (in absentiâ); and David Waterston (M.A.), Scotland, M.B., C.M. (with second-class honours), 1895. The degrees of Bachelor of Medicine and Master of Surgery were conferred in 10 cases and the degrees of Bachelor of Medicine and Bachelor of Surgery in 158 cases. The Cameron Prize in Therapeutics was awarded by the Senatus Academicus to Mr. W. M. Haffkine, C.I.E., in acknowledgment of the great practical importance of his researches on the prevention of plague by inoculation. The address to the graduates was delivered by Professor Hunter Stewart.

University of St. Andrews.

At a meeting of the University Court of St. Andrews held on July 28th the Lord Rector announced that he had received a letter from the law agent of the Marquis of Bute informing him that the Marquis of Bute proposes to offer to the University of St. Andrews the sum of £20,000 to be held as a fund for endowing a chair of anatomy, under the following conditions: 1. That the said sum of £20,000 shall be paid to the University not later than 10 years hence. The exact date cannot be specified, as it will depend on the completion of certain works at Cardiff. Interest at 3 per cent. will be payable to the University from the time of the appointment of the first professor until they receive the principal sum. 2. That the first presentation to the chair shall be in favour of Dr. Dusgrove, the present holder of the lectureship in anatomy in St. Andrews. 3. That the lectures shall be given exclusively in St. Andrews. 4. That the course shall meet the requirements of the two first "anni medici." 5. That before the beginning of the University session of 1901-1902 the approval of the Universities Committee of the Privy Council to the establishment of the chair under the foregoing conditions be obtained; and that the approval of Lord Bute or his representatives be obtained to any further conditions embodied in the ordinance instituting the chair. A postscript explained that the letter was written on the understanding that the University was prepared to make adequate arrangements for completing the permanent provision in St. Andrews of teaching necessary for the first two "anni medici." It was unanimously resolved to send the very hearty thanks of the Court to Lord Bute for his generous offer, also to print and circulate his letter and to consider the subject at a special meeting of the Court to be held on Saturday, Sept. 1st.

July 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Apothecaries' Hall of Ireland.

AT the annual meeting of the General Council of the Apothecaries' Hall of Ireland on August 1st the following were duly balloted for and elected to hold office for the ensuing year, ending July, 1901:—Governor: H. A. Auchinleck, F.R.C.S. Irel. Deputy Governor: G. Stritch, L.R.C.S. Edin. Directors: Francis G. Adye-Curran, M.D. T.C.D., F.R.C.S. Irel.; A. Atock, M.D., M.S., R.U.I.; John Evans, L.R.C.S. Irel.; W. V. Furlong, L.R.C.S. Irel., L.R.C.P. Edin.; John A. Johns, M.D. T.C.D.; Robert Montgomery, M.R.C.S. Eng.; Robert J. Montgomery, M.B. Dub., F.R.C.S. Irel.; R. G. O'Flaherty, M.B. T.C.D., L.R.C.S. Irel.; Christopher M. O'Brien, M.B. Durh., L.R.C.S., L.R.C.P. Irel.; Joseph A. Ryan, L.R.C.S. Edin.; James Raverty, L.R.C.S. Edin.; James Shaw, L.R.C.S. Irel.; and C. R. C. Tichborne, L.R.C.S. Irel. Representative on the General

Medical Council: C. R. C. Tichborne, L.R.C.S. Irel., D.P.H., &c. Secretary: Robert Montgomery, M.R.C.S. Eng.

Irish Women and University Education.

At the recent matriculation examination of the Royal University of Ireland 150 of the 555 successful students were women, a sufficient indication of the practical interest taken in university education by women.

The Belfast Hospital for Diseases of the Skin.

From the annual report submitted to the supporters of this charity on July 26th I find that 894 patients were treated during the year, of whom 37 were admitted into the wards. There is a balance in hand of £77 8*s.* 6½*d.* Special reference was made to the loss which the institution had sustained in the death of its President, the late Professor Hodges, M.D. R.U.I., who for such a lengthened period took the deepest interest in its work. Dr. H. S. Purdon, who for 35 years has been closely connected with the hospital, was appointed President in place of Professor Hodges.

Rainfall in July.

The rainfall in the past month amounted to 4·50 inches, there being 20 days on which rain fell, and the total rainfall for the year now amounts to 23·88 inches. This has been the wettest July since 1896 and the rainfall for the present year is 2½ inches over the average and 4½ inches more than last year.

The Outbreak of Typhoid Fever in Belfast.

At a meeting of the City Council of Belfast held on August 1st a report from the joint committees of improvement and public health was read in regard to typhoid fever in Belfast which has been already referred to in THE LANCET. It appears that the normal death-rate from typhoid fever in the city of Belfast is 4·46 per 10,000, while in Manchester it is 1·17 and 2·16 in Birmingham—that is, Belfast has about twice as much typhoid fever as a well-regulated manufacturing city should have. As to the causes, reference was made to the water-supply, sewerage, houses with bad privy and ashpit arrangements, presence of polluted old streams, and arrangements have been made to combat these causes. In the discussion which followed one of the speakers referred to the report of the new city analyst on the Belfast water which said among other things: "Judged by the ammonia process none of these waters (samples) can be considered high-class; they all contain more volatile solids than are usually found in Belfast water. The organic or albuminoid ammonia is rather high in all the samples, but is sufficiently high in Nos. 56, 36, 35, and 57 to place them among what may be called 'suspicious waters.' Nearly all the samples contained a good deal of matter in suspension, clearly indicating inefficient filtration." The same speaker said that a report by the city analyst made two years ago for the Water Commissioners was to the effect that the water was quite unimpeachable. On the day after the council meeting (viz., August 2nd) at a meeting of the Public Health Committee Dr. Lorrain Smith's report on the bacteriological examinations (which he has made for the committee) of the water-supply was received. He examined six samples of water with the following results: (1) yielded nothing; (2) gave negative results; (3) the colonies planted out from the residue directly and after cultivation in Parietti's medium were all found after examination to belong to ordinary water bacteria; (4) plates made from filter residue directly and from the growth in Parietti's medium were carefully examined but none of them stood the tests of detailed examination; (5) gelatin plates gave an average of 90 colonies per cubic centimetre; plates from the residue directly and from Parietti tubes yielded no colonies that stood the further tests; and (6) gelatin plates gave an average of 61 colonies per cubic centimetre. Plates from the residue directly and after cultivation in Parietti's medium gave no suspicious colonies. Dr. Lorrain Smith has in his possession the record of a series of observations made during 28 weeks of the spring and summer, 1899, extending from April to October. The highest number of colonies per cubic centimetre was 250, the lowest was 50, and the average was 119 cubic centimetres. The results of the present examination are very similar to those obtained in 1899, and in the number and quality of the microbes present the water now compares favourably with that supplied two years ago at the time of the general typhoid fever epidemic. "My examination now," says Dr. Lorrain Smith, "has failed to show that there is any recent increase in contamination or that the improvement observed during last summer has not been maintained." This report clearly shows that the water-supply as a cause of the present outbreak of typhoid fever may be excluded and that the question of its origin must be considered as arising from other causes, such as bad drainage, polluted soil, and defective sanitary arrangements as present in so many Belfast houses.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Anæsthesia during Labour produced by Injection of Cocaine into the Lumbar Arachnoid.

M. Doléris and M. Malartic have presented to the Academy of Medicine a very interesting communication on this subject. Their observations were made at the Maternity of Boucicaut on five women to four of whom cocaine was given for abnormally severe labour pains and in one case for the application of forceps. Although too few in number for the formation of a definite opinion, the result of these cases suggested the following conclusions:—(1) The uterine contractions became painless in from five to 10 minutes with doses of from one to two centigrammes (one-sixth to one-third of a grain); (2) with a dose of three quarters of a centigramme (one-eighth of a grain) they did not cease to be felt but they were painless for 27 minutes; (3) complete analgesia lasted one hour and 28 minutes, one hour and 47 minutes, and two hours and 15 minutes with doses of from one to two centigrammes; (4) the uterine contractions were more energetic, more frequent, and more prolonged after than before the injections; (5) in the interval between the contractions the uterus remained in a state of partial contraction for a variable period, on which account until further knowledge is gained it would be prudent not to use this method of inducing anæsthesia when turning might be required; (6) the loss of blood appeared to be less than usual, and in a case of placenta praevia the bleeding stopped spontaneously before the rupture of the membranes; (7) no effect was produced on the fœtus; (8) there was no ill consequence of any importance, the principal one being slight vomiting which soon passed off; and (9) in addition to its analgesic effect the injection of cocaine seemed to increase the contractility of the uterus and to act as a vaso-constrictor of the uterine vessels.

Tuberculosis in the Police.

Another example of tuberculosis incidental to occupation has been discovered similar to that occurring among attendants on the sick, post-office employés, and laundresses. M. Landouzy has just been examining the statistics of invaliding and death from tuberculosis registered during the last 10 years in the Paris police force. The number of officers of the Municipal Police varied from 8153 in 1894 to 7943 in 1899. Among an average annual strength of 7678 men there were in 10 years 825 cases of invaliding, and 230 of these, or 28 per cent., were on account of tuberculosis. During these 10 years there was a total of 491 deaths, of which 249 were due to pulmonary phthisis—namely, 49 per cent., or almost exactly one-half. When it is considered that the police are picked men, specially selected firstly, when they enter the army, and secondly, by the medical officers of the police at the time of their engagement, it will be seen that the police taken altogether suffer at least as much from tuberculosis as the post-office and telegraph employés, who show 25 per cent. of tuberculous diseases. The causes in fact are the same—namely, the unhygienic state of the police buildings where the men after their hours of duty come to rest in the midst of bacteria-laden dust brought in and scattered by the trampling of many feet. Several prophylactic measures have been already taken by M. Lépine, such as the providing of spittoons containing fluid in the police buildings, damp cleaning of the floor twice a day, and washing with plenty of water once a week. But it is in the internal arrangements of the police buildings that alterations are most required, for the rooms are low, dark, ill-ventilated, and overcrowded.

Sanatoria for Tuberculosis.

Seven years ago the Parisian sanatorium of Angicourt (Oise), the first and only sanatorium for tuberculous patients undertaken by the Assistance Publique, was commenced. It is not yet finished and its opening, which was to have coincided with the International Congress of Medicine, is

indefinitely deferred. Its cost is said to be going to be 7,000,000 francs. In contrast to this, the sanatorium of Hauteville-en-Bugey (Ain), built privately on an excellent mountain site under the auspices of the Lyons Association for the Tuberculous Poor, will be opened on August 23rd. Patients desirous of admission must present themselves at the Hôtel Dieu at Lyons on Monday, August 20th. The tuberculous poor of Paris, however, must wait.

August 7th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Bacteriology of Scarlet Fever.

Professor Baginsky and Dr. Sommerfeld of the Kaiser Friedrich Hospital in Berlin have made some important bacteriological observations on the bodies of children who had died from scarlet fever. In an article published in the *Berliner Klinische Wochenschrift* they report the result of the post-mortem examination of the blood and internal organs of 42 children; they also examined the blood of a living child in whom venesection was performed on account of dyspnœa, and the fluid obtained from another patient by puncture of the spinal canal. In the case of the deceased children the blood was taken from the heart immediately after death, and, moreover, pieces of the bone-marrow, the lungs, the spleen, the kidneys, the glands, the contents of the gall-bladder were examined. Cultures were made on bouillon and on agar, the result being that a streptococcus was found to be present in every instance, sometimes growing like a pure culture in the blood taken from the heart as well as in the bone-marrow. The presence of the streptococcus was independent of the character of the disease; it appeared in the very malignant cases, where death occurred within a few days, as well as in those in which death took place at a later stage from complications. The streptococci grew in series of from three to fifty individuals, the form varying according to the culture medium. Sometimes diplococci were found. They were easily stained with anilin colours and they retained the colour with Gram's stain. They grew on alkaline bouillon, agar, blood-serum, &c., and did not liquefy gelatin; the colonies were like those of the other species of streptococci. Experiments on animals showed that the cultures differed greatly in virulence; sometimes small quantities were sufficient to kill animals, in other cases the inoculations were harmless. The virulence of the streptococci could be augmented by repeated inoculations. The animals died with symptoms of septicæmia, swelling of the spleen, and hyperæmia of the kidneys and intestines, and pure growths of the streptococcus were found in their organs. The virulence of the cultures decreased after a few days, but when the cultures were preserved by ice it remained unimpaired for four or five weeks. The media in which the cocci were cultivated became very virulent, injections of pepton-bouillon killing animals within 24 hours. Professor Baginsky and Dr. Sommerfeld in their *résumé* do not assert that this coccus is the specific cause of scarlet fever, although they attach importance to the fact that it was found in all 42 cases examined. It would be possible to recognise a case as scarlet fever if this streptococcus were present in the body.

Intermittent Swelling of the Joints.

Dr. Theodor Benda has drawn attention to certain morbid conditions of the joints termed by him "hydrops articulorum intermittens." The characteristic symptom of this disease is that a joint, especially the knee-joint, becomes swollen at periodical intervals which are, as a rule, very regular. The swelling sometimes occurs every eighth, sometimes every eleventh, day, and so on. In a few instances the swelling appeared every day at the same time and lasted for about an hour. In the majority of cases the swelling was not very painful nor was the patient's state altered. Fever seldom occurred. The affection was sometimes the sequel of a traumatic lesion. The prognosis was very uncertain. In one instance the disease continued for 20 years; in another instance it terminated in recovery after 13 years. Complete recovery was obtained in about 33 per cent. of the cases, but in about 50 per cent. no alteration was perceptible, whilst in the remaining cases the attacks became less frequent. A great many remedies have been tried, but the results of treatment have not been satisfactory. Injections of iodoform and carbolic acid into the joint, and the administration of quinine and arsenic were tried, while electricity and balneological treatment were successful in one case and unsuccessful in another. Opinions differ very much as to the nature of the affection. Dr. Benda has found 55 cases described in the medical literature of different countries, not including two patients observed by himself. The efficacy of quinine in some cases has been ascribed to a connexion with malaria; rheumatic fever, syphilis, menstruation, and other causes have also been alleged. The majority of the writers on the subject are of opinion that the fits are due to a neurosis of the vaso-motor nerves, as some of the patients also suffered from other nervous symptoms, such as paralysis, epilepsy, hysteria, &c. Dr. Benda says that the etiology of the affection is not yet known. The causes of the periodicity which is the characteristic symptom of the disease are just as obscure as those of other periodical phenomena such as hemicrania and recurrent insanity.

Medical Congresses.

The German Association of Naturalists and Medical Men will meet this year at Aix-la-Chapelle. This town has been chosen as it is situated on the direct line of communication between North Germany and Paris and so that members returning from the Paris Exhibition may find it easy to attend the meeting. Aix-la-Chapelle has a considerable number of British visitors who may perhaps feel an interest in some of the subjects discussed. Papers will be read by the celebrated chemist Professor van 'tHoff on Inorganic Nature, by Professor Hertwig on the Development of Biology, and by Professor Naunyn on the Present Position of Clinical Medicine. Dr. von Drigalski will deliver an address on the expedition to the South Pole, and Dr. Haussmann will discourse on some problems connected with cells and their importance for organotherapy, &c. In the medical section the theory of neurons will be discussed.—Professor Virchow was elected honorary president of the International Congress of the Medical Press held in Paris from July 26th to 28th. The Association of the German Medical Press was represented by Professor Posner, editor of the *Berliner Klinische Wochenschrift*.

August 6th.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At recent sittings of the Scottish Conjoint Board held at Glasgow the following candidates passed the respective examinations:—

First examination (five years' course).—Ernest Gaunt, Yorkshire College, Leeds; John Clegg Pickup, Glasgow University; Archibald Frank Spinks, Anderson's College; Percival Henderson, University College, Liverpool; William Wallace Dempster, Queen's College, Belfast; Michael Joseph J. De Jong, Ceylon Medical College; William Arthur Magill, Queen's College, Belfast; William Miller Ramsay, St. Mungo's College; J. J. F. M. O'Flaherty, Queen's College, Galway; Michael Philip Desmond, Queen's College, Cork; James B. Patterson, St. Mungo's College (with distinction); Thomas F. Murphy, Queen's College, Cork; Norman B. Watch and George Hart, Anderson's College; and John H. Roberts, St. Mungo's College.

First examination (four years' course).—Adam Ardill, Dublin Schools.

Second examination (five years' course).—Robert Calder Blyth, Archibald M. Laurie, and William Douglas Cockburn, St. Mungo's College; Walter Ball, University College, Liverpool, and Anderson's College (with distinction); Henry Raynor Helsby, University College, Bangor, and St. Mungo's College; John Forbes Webster, and Reginald Norman Macdonald, Anderson's College; Alexander Russell Young and Thomas Joseph M'Caigney, St. Mungo's College; and Michael John M'Carthy, Queen's College, Cork.

Second examination (four years' course).—Thomas B. Trotter, Anderson's College; and Honorine Forbes, Calcutta Medical College.

Third examination.—Andrew Young and John Kean, St. Mungo's College; Alice Evangeline Brown, London School of Medicine for Women; Ethelbert Hearn, Firth College, Sheffield; Robert John Roberts, St. Mungo's College; Joseph Edwin Cooper, Newcastle School of Medicine; Rudolph de Mello, Grant Medical College, Bombay; and Ernest L. M. Hackett, Queen's College, Cork.

Final examination (and admitted Licentiate of the three co-operating authorities).—Percival Horace Rainbird and George Johnstone Campbell, St. Mungo's College; Alice Miles, Queen Margaret College; Sarah Harper Smith, London School of Medicine for Women; Albert Edward Ward, Anderson's College; John Thomson Malloch and Harry Miller Roberts, St. Mungo's College; Mary Eleanor Rocke, London School of Medicine for Women; Rupert Edward Moorhead, Anderson's College and Glasgow University; Charlotte Rudd, Ceylon Medical College

Richmond Goulden, Owens College, Manchester; David Crombie and Thomas Day Bird, St. Mungo's College; Richard Henderson O. Garbutt, Newcastle School of Medicine; Andrew Asher Brown, Surgeons' Hall, Edinburgh; Richard M'Kim Wilkin, Anderson's College and Queen's College, Belfast; Abraham George Sutton, Queen's College, Cork; Alexander Scoular, Anderson's College; James T. O'Connor, Queen's College, Cork; John James Lynch, Queen's College, Cork; Francis Fernandes, Grant Medical College, Bombay; Harold Robert Loverock, Royal College of Surgeons, Ireland; John Taylor, Glasgow Schools; Samuel Graham Kinloch, Edinburgh School; Rudolph de Mello, Grant Medical College, Bombay; Albert George Meares, Melbourne University; Daniel Samuel Coto and Augustus Daniel Kearney, Melbourne University; William John Buckmaster Queen's College, Cork; Thomas Randolph Hunter, Anderson's and St. Mungo's Colleges; Thomas Baird Trotter, Aberdeen University and Anderson's College; Patrick Brady, Dublin School; and Francis Joseph Nolan, Dublin School.

UNIVERSITY OF EDINBURGH.—The following is the official list of passes at the recent examinations for degrees in medicine and surgery:—

First professional examination.—M. I. Ali Khan. John Allan, D. I. Anderson, C. T. Ayana, E. A. Aylward, J. W. H. Babington, R. B. Burnetson, J. R. Bartholomew, W. J. Basson, Benjamin Baty, W. P. Beattie, D. W. Boswell, F. T. Bowerbank, F. R. Bremner, M.A., David Brown, W. S. Murdoch Brown, L. G. Bruce, G. L. Brunton, Mary T. Cameron, T. F. Campbell, T. E. Carlyle, V. T. Carruthers, Mildred M. L. Cathels, R. A. Chapman, W. P. Chrystall, D. M. C. Church, Lizzie M. S. Clark, John Clarke, M. L. Cohen, B.A., A. G. Coullie, T. E. Coulson, James Craw (with distinction), G. A. Davies, Robert Donaldson, M.A., S. E. Douglas, C. E. Dumanoire, E. J. Elliot, Hugh Ferguson, J. M. R. Flament, W. H. Foxsyth, W. J. Fraser, N. J. H. Gavin, H. V. Goldstein, Eleanor A. Gorrie, Percy Gosnold, B.A., Thomas Gowans, J. M. Graham, William Grant, W. W. Greer, E. J. Griffiths, Elizabeth C. Gunn, T. M. Guthrie, P. A. Harry, A. W. Hogg, M. A. Huk, M. M. Huk, J. H. Hume, K. U. A Innis, Ada Jackson, John Jardine, William Jarvis, J. M. Johnston, J. H. H. Joubert, G. P. Joy, S. F. Jung, G. F. S. Landon, F. E. Larkins, S. W. S. Leary, A. G. Leitch, A. J. Lewis, C. W. Lewis, B.A., James Lochhead, M.A., D. H. C. MacArthur, S. A. M'Clintock, William M'Conaghy, J. S. MacDonald, J. W. M'Ewan, J. P. M'Gowan, M.A., H. R. Macintyre, James Mackenzie, Amy M. Mackintosh, William MacLaren, Neil M'Leod, Alexander MacRae, M. M. Mamourian, L. S. Milne, K. A. Moody-Stuart, W. M. Munby, D. S. Murray, A. W. Neill, C. D. O'Neal, Armand Pampellonne, Bernard Pickering, Florence M. S. Price, D. S. R. Rao, H. S. Reid, Margaret H. Robertson, Thomas Robertson, Joseph Robinson, B.Sc., S. C. Roy, C. S. Ryles, A. I. Shepheard-Walwyn, F. R. Sinton, L. H. Skene, C. J. Smith, E. H. Smith, G. M. Smith, R. A. L. van Someren, Patrick Steele, George Stewart, H. M. Thompson, Archibald Tedrick, Rose C. Townend, Caroline Twigge, G. H. Ussher, F. L. de Verteuil, William Waddell, Thomas Walsh, R. H. Watt, W. H. Welsh, D. W. Wilton, W. B. Wishart, Thomas Wright, and Margaret C. W. Young, M.A.

Second professional examination.—Farhat Ali, W. L. L. Alston, Lewis Anderson, W. W. Anderson, R. G. Archibald, James Arthur, Nina H. Beath, Constance A. Bennet, J. G. Briggs, W. A. Brown, G. G. Buchanan, W. C. Burton, E. E. Cassaday, R. V. Clark, M.A., Maurice Davies, A. R. Douglas, C. B. Drew, Percy El-Karey, John Fairbairn, A. B. Flett, Agnes J. Gardner, P. E. H. Guiseppi, W. L. M. Goldie, R. G. Gordon, Philip Hallam, D. J. Hamman, Frances M. Harper, A. O. Hooper, William Hume, John Hunter, Arthur Hutley, Bertha Jex-Blake, Saiduzzafar Khan, E. A. King, W. E. Knight, Hermann Kramer, Vivian Langmore, Abraham Leach, Duncan Lorimer, A. W. B. Loudon, W. F. Macdonald, Daniel Mackinnon, S. W. Maclean, J. J. M'Millan, E. L. Meynell, R. C. Monnington, A. E. Morton, E. J. Morton, P. H. Mules, R. S. Munro, Frank O'Neill, Sophie Palmer, Herdman Porter, E. C. Prichard, Agnes M. Pringle, A. M. Pryce, A. F. H. Rabagliati, J. J. Redhead, E. M. Reece, R. E. Russell, C. W. V. Rutherford, David Sandler, Meurice Sinclair, G. W. R. Skeen, G. D. Sloan, D. W. Standley, Elbert Steyn, G. C. Trotter, Philip Vickers, J. F. van de S. de Villiers, John Wallace, B.Sc., George Wright, and E. E. Wood.

Third professional examination.—D. M. Aitken, M.A., R. V. C. Ash, J. W. Barrack, E. S. Brett, D. G. Carmichael, A. W. S. Christie, R. V. Clark, M.A., H. L. Clift, W. I. Dunn, O. J. Evans, A. H. Firth, G. A. Forrest, Robert Hamilton, P. J. Hay, John Jamieson, G. A. Jolly, E. W. Lewis, C. H. Lindsay, Samuel Lyle, Harriet E. M'Cloghry, H. K. Macdonald, Wilfrid M'Farlane, N. F. MacHardy, George M'Neill, Thomas Mill, Robert Morison, William Murray, J. G. Peebles, E. T. Potts, L. T. Price, F. L. Rigby, J. S. E. Robertson, A. L. Roxburgh, G. W. R. Skeen, C. W. Somerville, B. A. Spence, C. S. Steavenson, I. S. Stewart, G. C. Strathairn, John Sullivan, H. P. Thomson, E. J. Tyrrell, A. G. Waugh, and Ada Wilkinson.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Professor A. Born of Breslau, aged 50 years. His subject was anatomy and more particularly embryology.—Dr. Moussier, surgeon to the Nantes hospitals.—Dr. Skene, formerly Professor of Gynæcology in Long Island College Hospital, Brooklyn.—Dr. Shakespeare, a well-known Philadelphian ophthalmic surgeon.—Dr. Sutuguin, formerly *docent* of Gynæcology in the St. Petersburg Medical Academy.—Dr. John Ashhurst, the well-known American surgeon. He was formerly Professor in the University of Pennsylvania.—Dr. Hermann Dohnberg, Professor of Ophthalmology in St. Petersburg, has been assassinated.—Dr. Kristeller, *privat-docent* of Gynæcology in Berlin.—Dr. B. D. Howard, formerly Professor of Surgery in the University of Vermont.

NEWTON ABBOT WORKHOUSE.—At the meeting of the Newton Abbot (Devon) Board of Guardians held on August 2nd it was reported that £19,000 had been already expended upon the new building. The guardians resolved to apply to the Local Government Board for permission to borrow an additional £5500 for the erection of a new boardroom and also for providing receiving wards and tramps' wards.

THE OWENS COLLEGE.—The council has appointed Mr. F. A. Southam to be Professor of Clinical Surgery in place of Mr. W. Whitehead, who has resigned, and Mr. G. A. Wright to be Professor of Systematic Surgery in place of the late Mr. T. Jones. These appointments are subject to the confirmation of the Court of Governors which will meet in October. The council has also appointed Mr. W. Thorburn to be Lecturer in Operative Surgery and Mr. Joseph Collier to be Lecturer in Practical Surgery.

PRESENTATION TO A MEDICAL MAN.—In connexion with the legal proceedings taken against him twelve months since (which resulted entirely in his favour), the heavy law expenditure which he incurred, and his subsequently failing health, Mr. James Joseph Tracy, M.B. R.U.I., of Cork, has just been presented with a testimonial. At a recent meeting of his professional brethren it was unanimously resolved to present Dr. Tracy with an address and a purse of sovereigns as tokens of sympathy and esteem. Dr. N. J. Hobart made the presentation on behalf of the subscribers.

INOCULATION FOR THE PLAGUE.—The annual report of the Presbyterian Mission Hospital at Miraj, under the charge of Dr. W. J. Wanless, has just been issued. In reality it deals with parts of the years 1898 and 1899. For three and a half months in 1898 and the early months of 1899 plague prevailed in the town of Miraj resulting in the practical closure of the hospital and dispensary during this time. A full 12 months' work in either year could not therefore be recorded. With regard to the plague the report says the great benefit derived from inoculation is evident from the following: there were among the once inoculated 39 attacks and 22 deaths, and among the twice inoculated two attacks and one death. The population in the town and fields of uninoculated persons from Sept. 13th, 1898, to March 13th, 1899 (six months), could not have been less than 1300. Among these uninoculated persons there were 1314 attacks and 1092 deaths, a rate (to the population) of 10·1 per cent. of attacks and a rate of 8·4 per cent. of deaths, and a percentage of 83·1 of deaths among the attacked, while among the once inoculated the rate of attacks (to the population) was 1·9 per cent., and of deaths 0·8. In the twice inoculated the rate of the attacks was 0·4 per cent., and the rate of deaths 0·2 per cent. The total number of inoculations against plague with Haffkine's prophylactic serum performed in this dispensary to Dec. 31st, 1899, was 4274.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, AUGUST 2ND.

The Vaccination Question in Scotland.

MR. EDMUND ROBERTSON asked the Lord Advocate whether his attention had been called to the recent conviction in the Dundee Sheriff Court of a number of men for failing or refusing to have their children vaccinated, and to the fact that accused pleaded conscientious objections, and on conviction preferred to go to prison rather than pay the fines imposed; whether similar cases have occurred in other parts of Scotland; and, whether, having regard to the difference now existing between the laws of England and Scotland on this matter, and to the dissatisfaction created thereby, the Government would consider the question of the assimilation of the laws of the two countries on this matter.—The LORD ADVOCATE replied: I have seen a report of the Dundee case referred to and I am aware of similar cases in Aberdeen and Kirkcaldy. I believe such cases, however, to be very few. In the six convictions at Dundee referred to five went to prison and one paid the fine. One of the five paid the fine *pro tanto* after a detention of one day. I have reason to believe that there is a great preponderance of opinion in Scotland in favour of the existing law, and the Government do not propose to consider the question of assimilating the Scotch law to the English law.

Water Filters for South Africa.

Dr. FARQUHARSON asked the Under Secretary of State for War whether, considering the spread of enteric fever in South Africa, he would consider the possibility of increasing the number of pocket Rustem filters served out to the troops on active service there.—Mr. WYNDHAM replied: No filters of the kind referred to have been issued

the troops. The only filters that have been issued are of the Berkefeld and Stack and Brownlow type.

FRIDAY, AUGUST 3RD.

Vaccination Questions.

Mr. HEDDERWICK asked the President of the Local Government Board how many calves were kept by the department as reservoirs of lymph for vaccination purposes; how many of the animals so used were sold annually as food for the people; and where the sales took place.—Mr. CHAPLIN replied: The average number of calves now vaccinated weekly at Lamb's Conduit-street is 17. All the calves from which lymph has been collected are, within the next few days, slaughtered under veterinary supervision and the calves passed on veterinary authority as sound are sold in the Central Meat Market, Smithfield.—Mr. CHANNING asked the President of the Local Government Board whether, seeing that the opinion of the law officers of the Crown, based on the case of Bramble *v.* Lowe, by which he had justified the action of the Board in treating vaccination officers as servants of the Board and not as subject to the directions of the guardians, referred only to prosecutions under Section 31 of the Act of 1867, the opinion of the law officers had been taken on the extension of this practice of ousting the power of the guardians to direct the proceedings of their vaccination officer to prosecution under Section 29 of the Act of 1867; and whether he would give the opinions of the law officers as a parliamentary paper. — Mr. CHAPLIN replied: The hon. Member is under a misapprehension in supposing that the Local Government Board have treated the vaccination officers as their servants. As the Board explained in their circular of Oct. 21st, 1898, the power and the duty of taking proceedings are vested in the vaccination officer under the Vaccination Act passed prior to the Vaccination Act of 1898 without any order of the board of direction from the guardians. The opinions which the law officers have given to this effect referred to prosecutions both under Section 29 and Section 31 of the Vaccination Act, 1867; but it would be opposed to the established practice to publish these opinions.—Mr. WOODS asked the President of the Local Government Board whether he was aware that the minimum fees fixed by the Vaccination Order, 1898, pressed heavily on the local ratepayers at Wigan and other places, and that there was paid in the Union of Wigan for the year ending Lady Day, 1898, £516 9*s.* 5*d.*; for the year 1899, £433 5*s.*; and for the year 1900, £1541 7*s.* 7*d.*; and whether, in view of these charges, he would consider the whole matter with a view of placing them on a more reasonable basis. — Mr. CHAPLIN: We have not got the figures for 1900 which show the increase in expenditure at Wigan, but the establishment of a system of domiciliary vaccination has necessarily added to the cost of vaccination, as the duties of the officers have in consequence been very considerably increased. Moreover, the amount of the fees to some extent depends on the number of successful vaccinations, and I am glad to say that this number has been largely augmented since the Vaccination Act of 1898 came into operation. In the Wigan Union there was an increase of about 60 per cent. in the number of successful vaccinations in 1899 as compared with 1898. I have, however, received other representations on this matter and I am, as I always have been, willing to consider whether an alteration should be made in the minimum fees prescribed by the vaccination order; but I think we should have some further experience before determining whether this course ought to be adopted.

Pollution of the Thames.

Viscount SANDON asked the President of the Local Government Board whether his attention had been called to a recurrence of pollution of the river Thames near the sewage pumping stations at Halfway Reach and Barking Reach; and whether he would cause the necessary steps to be taken to obtain an abatement of the nuisance as a precaution against danger to health of those engaged upon the river.—Mr. CHAPLIN replied: I have made inquiry on this subject and I am informed that it is the recent hot weather which is mainly responsible for the nuisance complained of in the part of the river referred to in the question. I learn from the London County Council that they are fully intent on further improving the condition of the river and that they have undertaken several large works with that object. The Local Government Board have no power to take any steps in the matter.—Mr. STEPHENS asked the President of the Local Government Board (1) whether his attention had been called to the fact that during the year 1899 38 sewage overflows dischargod sewage into the Thames on its northern side within the London area; and (2) seeing that such discharges of sewage were liable to take place whenever the rainfall exceeded one-tenth of an inch and that the existing obligations of law compelled local authorities to admit the combined drainage of sewage and water to their sewers, whether, in the next session of Parliament, it was his intention to introduce a Bill to enable the local authorities to keep separate, if they desired to do so, the sewage and the water drainage of their districts.—Mr. CHAPLIN replied: No, sir; my attention has not been called to the facts referred to and I have no information to show how far they are as suggested in the first paragraph of the question. With regard to the second paragraph, local authorities have the power to provide, and they have in some instances already provided, separate systems for sewage and water drainage. The further legislation suggested on the subject, it appears, would raise questions of considerable importance which would involve heavy expense, and in any case I am not prepared to give any pledge with regard to legislation next session.

Enteric Fever in South Africa.

Sir WALTER FOSTER asked the Under Secretary for War for the figures as to the number of admissions at Bloemfontein and Kroonstad for enteric fever during certain weeks and the number of deaths.—Mr. WYNDHAM replied: The figures are as follows, viz., Bloemfontein, week ended June 8th, 487 admissions, 98 deaths; week ended June 15th, 213 admissions, 64 deaths; week ended June 22nd, 221 admissions, 52 deaths. Kroonstad, week ended May 25th, six admissions, no deaths; week ended June 1st, 83 admissions, 12 deaths; week ended June 8th, 18 admissions, 18 deaths; week ended June 15th, 66 admissions, 11 deaths.

MONDAY, AUGUST 6TH.

The Remuneration of Civil Practitioners in South Africa.

Mr. ELLIS GRIFFITH asked the Under Secretary of State for War whether his attention had been called to the fact that civil medical officers in South Africa did not get colonial allowance, though such allowance was allowed to every other person now serving in the British army in South Africa; and whether he would take steps to remedy this state of affairs.—Mr. POWELL WILLIAMS, replying for Mr. WYNDHAM, said: The civil medical practitioners engaged for service in South Africa are paid according to the special terms for which they engaged—viz., pay at £1 a day, field allowance at 3*s.* 6*d.* a day, servant's allowance, Government horse with forage, and field rations while in the field, with a gratuity of two months' pay at the expiration of their contract. They accordingly receive higher emoluments than many of the officers of the Royal Army Medical Corps. The Secretary of State for War sees no reason for making any addition to their emoluments.

The South African Commission of Inquiry.

On the motion for the second reading of the Appropriation Bill Mr. BURDETT-COUTTS complained that there had been no opportunity for discussing the constitution as a whole of the Commission appointed to inquire into the care and treatment of the sick and wounded during the South African campaign, but without going into the question then the hon. Member set himself to show that the Commission was without the powers essential to bringing out the whole truth, and that the great interests involved in the inquiry would be imperilled, if not defeated, by the course which had been followed. The Commission, he said, had neither the power to take evidence on oath nor to compel the attendance of witnesses and consequently went forth at the mercy of one side and one interest in the inquiry and that the interest and side most involved in its own exculpation. The Commission had gone out to South Africa where nine-tenths of the evidence in the case was under the control of the Army Medical Department or some other department of the War Office. Their hand reached over the whole field of witnesses and of course they would organise the evidence and select the witnesses. While on the one side there would be this powerful organisation, on the other there would be absolutely nothing except the voluntary act of witnesses 99 out of 100 of whom believed, rightly or wrongly, that their future would be prejudiced by coming forward. The hon. member read to the House extracts from a number of letters by military and civil surgeons and others, in which reference was made to the apprehended consequences of coming forward with evidence, and, in conclusion, he asked the Government whether it was not still possible to increase the powers of the Commission.—Mr. BALFOUR, in reply, said that there had been few commissions with the power of taking evidence on oath and compelling the attendance of witnesses, and he pointed out that if this Commission had received such power it would have found it difficult to exercise it in self-governing colonies. As to the other issues, he thought that the hon. member was very ill-advised in raising them, especially at this time, when the Commission had embarked upon its inquiry and after the hon. member had himself been examined before the Commission.—Sir WALTER FOSTER expressed the opinion that the Government had taken too narrow a view of this inquiry. For himself he had no desire to obtain the slightest party advantage one way or the other, but he did desire that they should have a searching inquiry and get full knowledge of how it came about that their heroes in Bloemfontein were allowed to die in bell-tents in the manner described by the witnesses before the Commission. To this knowledge every citizen was entitled. With regard to the general situation he considered it was an enormous blot upon the campaign that there should have been between 16,000 and 17,000 cases of typhoid fever amongst our troops; to him that circumstance was enough to show that there had been something wrong in the administration in South Africa.—Colonel BLUNDELL, speaking as an old soldier, said that he had every confidence that the Commission would conduct a proper inquiry and arrive at a proper conclusion.—The House then proceeded to the discussion of other subjects.

TUESDAY, AUGUST 7TH.

Inoculations at the Brown Institution.

Mr. MOSS asked the Home Secretary if his attention had been called to a statement by the superintendent of the Brown Institution that the inoculations with rabies performed in that institution were of no use except for the purpose of compiling statistics; and whether, seeing that these inoculations with rabies inflict suffering on a number of animals, he would take the necessary steps to prevent their continuance in that institution in future.—Sir MATTHEW WHITE RIDLEY replied: The superintendent of the Brown Institution states that the question does not accurately represent any opinions expressed by him. He considers that the inoculations referred to afford the only means of determining the existence or non-existence of rabies in a suspected animal.

The Increase of Vaccination in England.

Sir WALTER FOSTER asked the President of the Local Government Board whether he could state the number of certificates of successful primary vaccination received by the vaccination officers during the year 1899 as compared with 1898, and the number of such certificates received for the first six months of this year as compared with the similar period of the years 1898 and 1899.—Mr. CHAPLIN replied: The number of certificates of successful primary vaccination received by vaccination officers during 1899 was 669,349 as compared with 500,314 during 1898, being an increase of 169,035 or 33·9 per cent. I have not received returns as to the number of such certificates during the first six months of the present year.

Medical Reinforcements for South Africa.

Sir WALTER FOSTER asked the Under Secretary of State for War if he could state the strength of the reinforcement of trained men of the Royal Army Medical Corps which it had been recently decided to send out to South Africa.—Mr. WYNDHAM replied that the strength of the reinforcements was 300.

The Remuneration of Civil Practitioners in South Africa.

Mr. WYNDHAM, replying to questions on this subject, said: The position of these gentlemen differs in one important particular from that of officers of the Royal Army Medical Corps. The latter receive rates of pay which are calculated with reference to the general services which they have to perform at all times and in all parts of the world. The conditions of the present war are, however, unusual as regards the specially high cost of living in South Africa, and it was therefore thought reasonable that special colonial allowances should be granted to them to enable them to meet this extra expense. The case of the civil surgeons is quite different. They made a special

contract for service in South Africa during the present war, and there is, therefore, nothing unforeseen in the conditions of their service which we feel called upon to meet by an alteration in their favour in the terms of the contract. As a matter of fact, they receive higher emoluments than many of the officers of the Royal Army Medical Corps. My attention has been called to the fact that civil veterinary surgeons are receiving colonial allowances. That is so, the reason being that they are paid at the rate of army veterinary surgeons and not at a special rate calculated with a view to the present war.

WEDNESDAY, AUGUST 8TH.

The South African Commission of Inquiry.

Mr. EDMUND ROBERTSON asked the Leader of the House whether he could give any estimate of the time when the report of the Commission on the care of the sick and wounded during the South African campaign might be expected.—Mr. BALFOUR replied that he had no authoritative estimate but he knew that the Commission did not anticipate that the South African inquiry would occupy any very considerable time.

THE SOUTH AFRICAN COMMISSION.

WEDNESDAY, AUGUST 1ST.

THE Commission appointed to inquire into the care and treatment of the sick and wounded in the South African campaign resumed their sitting, with Lord Justice ROMER in the chair, at Burlington House, this being their last meeting in London before going out to South Africa. The meeting lasted for about six hours and a large number of witnesses were examined.

The CHAIRMAN at the start made an expianatory statement with regard to the conduct of the proceedings of the Commission. So far, he said, the whole of the evidence had been taken in presence of shorthand writers and made public, and this practice would be continued except in certain circumstances. It had been stated to the Commission that some witnesses who could give useful evidence might be deterred by fear of consequences from coming forward and giving information. The Commissioners had felt some difficulty with regard to this subject, but they were determined that information should not be withheld from them on any such ground and on consideration they had come to the conclusion that the names of witnesses who felt this apprehension or the particulars by which they could be identified should not be printed or published if they so desired it. The Commissioners, however, would take care that witnesses should not be permitted to use the withholding of their names as a cloak for making personal attacks upon individuals.

Mr. R. O'CALLAGHAN said in the course of examination that he went out to South Africa as surgeon-in-chief of the Langman Hospital. At Cape Town, where they were detained for several days, he visited the base hospitals and he could say of them that they were as absolutely perfect as one could expect or wish for. They reached East London on March 26th, and though all the while they were urging the authorities to hurry them forward they did not disembark until the day after the arrival of the ship. The railway authorities at East London were quite alive to the urgency of hospital aid at Bloemfontein, for they had a special train to take forward the Langman Hospital, but all along the line they found themselves being thwarted by the military authorities whose great anxiety was to get through military stores. They had to leave East London without two of their trucks. As for those they got away, it was with the greatest difficulty that they got them forward; they had practically to sit on them and say that if the trucks did not go forward they themselves would not move. If they had not done this the trucks would have been turned into sidings. After a journey of three or three and a half days they reached Bloemfontein on April 2nd, and owing to the other stores not arriving from East London they were absolutely useless for four days. No words were strong enough to describe the dilatory fashion in which the stores of the Langman Hospital were treated, for it must be remembered that the cry for hospitals at Bloemfontein at this time was almost as urgent as the cry for help from the Legations in Peking. The Langman Hospital was intended for 100 beds, but there was such a rush of cases that they took over 50 more beds; before taking these over, however, they made it a condition that they should have utensils and nurses for them. Before leaving this country they applied to the War Office and the Director-General to be allowed to take nurses, but they were refused, though when they got to Bloemfontein they received the services of nurses. At Bloemfontein there were utensils and other things they could not get from the authorities, but fortunately Mr. Langman was with them and he went and bought the things at his own expense. That, witness thought at the time, was rather hard lines considering that they were in the enemy's country. In the hospital everything went smoothly and successfuly once it had been started, and so far as he was aware nobody had any cause for complaint. They never got all the fresh milk they wanted. He believed that if a due proportion of medical stores and equipment had been allowed to come up the railway a great deal of the criticism passed upon the medical arrangements would never have been heard. He saw two field hospitals near the Langman Hospital at Bloemfontein. They had been turned into stationary hospitals and no doubt there were overcrowding, undermanning, and want of nurses. While he said that he also said that no men could have worked harder than did the officers in these hospitals. The want of stores he put down to culpable leniency shown to the Free Staters.

Lieutenant C. A. LEE of the New South Wales Mounted Rifles gave evidence as to the excellence of the treatment he received in various hospitals whilst suffering from enteric fever. He said that he had the hospitals to thank for being able to appear before the Commission.

Captain THOMPSON of the 1st Australian Horse said that he became ill with dysentery and enteric fever in May between Kroonstad and Johannesburg and the regimental surgeon did all he possibly could for him. Witness was anxious to get on to Pretoria and he kept up the march, the surgeon being hopeful of staying the progress of the trouble. When, however, an engagement was expected witness was ordered back to Kroonstad, to which place he was conveyed in a Scotch cart with another officer. They found the hospital full and they were accommodated in a hotel which was turned into a hospital. There were 100 odd officers in this hotel, which had two surgeons, two trained orderlies, and some convalescent men who assisted in attending the patients. When they left Bloemfontein nobody thought there would be so large a number of cases of enteric fever and dysentery. The patients got all the care and attention they could reasonably expect under the circumstances. They had fresh milk when it could be got and always condensed milk. He knew of cases of beds, mattresses, and other things in the houses of the town being requisitioned. What struck him most of all was the wonderful amount of work got through by the medical men. Many regimental surgeons, especially after an engagement, were out all night with the wounded and on the following day they were employed with their batches of sick. Witness was in command of a squadron of cavalry attached to General French's division, and he really thought the medical men were too solicitous about the men's health and unnecessarily reduced the commands.

Mr. RUDYARD KIPLING, the next witness, said that he landed at Cape Town on Feb. 5th, and from then until the end of the month he was generally in and out of the Cape Town hospitals. He talked with the medical officers, asking them amongst other things whether they had everything they required for their patients. They replied that there was no particular strain upon the hospitals and that they had everything they wanted. When he spoke to the nurses and said that he could get things from the Absent-Minded Beggar Fund, they said that they wanted pyjamas very badly, but they added "Don't send them to the store issue department, for they will never come out; bring them to the back door." They were taken to the back door in a Cape cart and given over quietly to the nurses, and thus they reached the patients without any delay. In this way pyjamas were also supplied to the hospital train. It was reported to him indirectly that there was no medicine in the Maitland Hospital beyond a little boric acid and some quinine pills, and from the Absent-Minded Beggar Fund he sent over a few pounds' worth of medicines. They were sent privately, in the same fashion as the pyjamas, but, of course, they were given not to the nurses but to the surgeons. What he did was with the object of saving time. He saw the wounded in a hospital train coming down from the front. There was nothing bad there and everybody seemed to be working very hard. When he got to Bloemfontein, the enteric fever was only beginning and there was no strain upon the medical arrangements. He could see, of course, that there was no enthusiasm about sick cases; they were slow and uninteresting, whilst wound cases were interesting and quickly cured. When he returned to Cape Town, he went over the hospitals again. He found them perfectly clean and everybody was working very hard, but there was always this quiet complaint about the persistent slowness in getting what was required. He did not visit the Woodstock Hospital; he saw it from a distance, and the place was simply unspeakable; the air was foul and stank.

Colonel MULCAHY, the officer in charge of the Royal Army Clothing Department, presented to the Commission a series of tables showing the quantities of supplies of hospital clothing sent out to South Africa. These tables, the CHAIRMAN said, he and his brother Commissioners would examine and study during the voyage out. With regard to stationary and general hospitals Colonel MULCAHY said that in every case they shipped with them 50 per cent. of reserve in addition to the equipment. If the complement of gowns for a stationary hospital was 100 they put 150 on board. The only case where in the tables it might appear there was delay in meeting requisitions was a case where certain shirts were wired for on March 25th and a portion of these shirts were not sent out until July 21st. That meant that the particular pattern of shirt used in the hospital was not sent out, but other patterns were sent out to the number of over half a million. What were sent out were not hospital pattern shirts, but others which were practically as useful. The requisitions were quickly answered. Where they could not supply the exact article asked for they substituted other items. For instance, when a certain number of gowns could not be supplied they sent waistcoats instead. Pyjamas were not a recognised article of military hospital clothing: they had not been approved by the authorities at home; but a flannel shirt and a pair of drawers were the regulation for the military hospital and these could be used as pyjamas, and ample supplies of both articles had been sent to South Africa.

Mr. J. A. MORRISON, M.P., lieutenant in the Grenadier Guards, gave an account of his hospital experiences at Modder river and Wynberg, his general comment being that he noticed nothing deserving of complaint.

Mr. G. L. CHEATLE said that he arrived at the Modder river on Jan. 31st and found the hospitals there working perfectly. He saw no patients lying on the floor or without beds. He was there two months altogether. Lord Roberts put a hospital in his hands with the object of treating the cases of the more severely wounded. He saw the wounded from Paardeberg and Kimberley. On one day 779 cases arrived from the former place. They were all put in bed, but they were mostly afterwards sent off by train. After the first 24 hours there were no deficiencies whatever. He bought the necessary things and fed the patients, and they wanted for nothing. After the two months at the Modder river he went to Kimberley and afterwards to Bloemfontein. At the latter place he saw the Guards Brigade hospital; it had 400 patients and was very much crowded. They were a mixed lot of cases of enteric fever and dysentery, but no wounded at all. They were housed in bell-tents, marquees, and iron buildings. All the tents were entrenched and the men had mackintoshes and blankets, and in some cases red pyjamas. They complained very much of being overcrowded. They did not get any fresh milk that he knew of. The surgeons complained of the amount of work. He advanced from Bloemfontein with General Pole-Carew. When men got wounded and required treatment he stopped behind and looked after them in the Boer houses. The wounded were very well attended to in that advance and got everything which they required. Witness was with the advance to Pretoria all the time and of course passed through Kroonstad. He could only speak as to the care of the wounded; he could not speak of the typhoid fever or dysentery cases. As far as the treatment of the wounded was concerned, they had everything—plenty of dressings—and he never had any difficulty whatever. They had sufficient orderlies, and whenever they left a man behind they left with him a surgeon and an orderly. He was for two or three days outside Pretoria. Then he went on to Silvertown and brought back

the wounded to Pretoria and then he came home. At no time did he feel hampered by the want of medical equipment.

Lieutenant-Colonel F. BARROW, A.M.S., Principal Medical Officer of No. 9 General Hospital said that the hospital was equipped at the Albert Docks, London, for 500 rank and file and 20 officers and that it reached Bloemfontein about April 7th. Owing to the block in the railway service they had to wait for 10 or 12 days for the arrival of the equipment. The railway people said that they would forward it from Port Elizabeth and then it only came in driblets. What was said was, food first, then ammunition, and then medical equipment, and of course witness agreed with that view of the case. They were practically without anything to do for a fortnight. As he said, they were equipped for 520 patients, but they got 1500, 1600, and 1800 patients dumped down upon them. They had 88 marquees, and he asked for 25 more and got them; it was all they had. They had a surplus of sick mild cases. They requisitioned bell-tents for them and got them at once, and into each bell-tent they put two or three patients, but no serious cases. If cases became serious they were sent from the bell-tents to the marquees. He considered that the hospital was very fully equipped. He had been on service three or four times and he never saw a more complete hospital. They got beds made locally and on these they put mattresses in the bell-tents. All the marquees had proper spring mattresses. In the bell-tents they had the improvised local pattern of bed, with locally provided mattresses which answered very well. Their water-supply was inadequate owing to the break-down of the waterworks. They were entitled to 60,000 gallons of water per day and they found difficulty in getting 6000 gallons from two wells. They were told to boil the water, but they had no firewood and there were no trees to cut down. This state of things lasted for three weeks until they got a supply of coal and wood from the base. Naturally they ran short of regulation army stores. They had to requisition persons who were not trained orderlies, but they did their best and, indeed, did very well. He went morning, noon, and night round the tents and asked for complaints and he never heard one. He heard one patient say to General Kelly-Kenny that he had had nothing to eat for eight days, but as a matter of fact this man had had 11 pints of liquid, and because it was not solid food, which was not indicated in his case, he considered that he had had nothing to eat. What he had had consisted of bovril, beef-tea, milk, and jellies. Witness himself used to sleep in a bell-tent. He personally stopped the supply of fresh milk because of the risk of contamination owing to the dirty habits of the Kaffirs. He preferred the condensed unsweetened milk because it was impossible to contaminate it. They had tons of condensed milk, and 2000 or 3000 tins of it were used every day. As to the men's rations, there were frozen mutton and fresh meat, and very often they had to bury it because, although the ration had been drawn, the patient was unequal to eating it. War meant waste, and, no doubt there was waste in this connexion. Later he issued orders not to draw the full rations because they had milk, bovril, and medical comforts taking their place. As to the bell tents they had no overcrowding at any time in connexion with No. 9 Hospital. In fact, he never saw a thing more splendidly done by the Government, and goodness knew what the bill would be. The officers and the rank and file had exactly the same treatment as far as medical comforts were concerned. There were lots of patients who arrived with absolutely nothing the matter with them. There was one orderly to three tents, and when there was very little the matter with the patients that was quite sufficient. If there had been any water on the floor of the tents he should have seen it. The fact was they were on a slope and the site had been chosen by a board of army medical men. He had not sufficient trained men because no one had anticipated such a rush of sick. He did not see Mr. Burdett-Coutts at the hospital; if he was there he ought to have had a pass. As to the buildings in the town being taken for hospital purposes they were pesthouses. It was far better to treat a man in the open air than in an insanitary room. There could be no doubt that the houses were insanitary and the bucket system as carried out in South Africa was simply abominable. He would not put cattle into some of the houses. They had a large staff of female nurses in the marquees, and the reason why they had not them in the bell tents was that they were not required for mild cases. He confessed that they were short of utensils. As for blankets he got plenty of them; he requisitioned 2000 on one day and got them at once.

Dr. CHURCH: We have had it suggested that the officers did not like to ask for what they wanted.

Lieutenant-Colonel BARROW: If I did not get what I wanted there was a row. I never asked for anything that I did not get. I asked for transport and they said it was impossible, but I got it all the same. I got my own transport. I think that a field hospital will never be complete until it has its own transport. I got my transport after a personal interview and explaining the difficulty.

Dr. CHURCH: You had a lot of trouble about the returns?

Lieutenant-Colonel BARROW: Well, I neglected most of the returns and the statistics also. I got many urgent telegrams from Cape Town asking "where are your returns?" I took no notice of the telegrams.

The CHAIRMAN: Were they unnecessary and cumbrous?

Lieutenant-Colonel BARROW: They were necessary, but there is great difficulty in furnishing them when working at high pressure.

Dr. CHURCH: Did you ever see 10 men in a bell tent?

Lieutenant-Colonel BARROW: Never. I went round frequently in the day and dodged round and looked into them. There might be 10 in a tent from a train arriving at three in the morning, but they would not be there long after daylight.

Dr. CHURCH: Are the men afraid to make complaints?

Lieutenant-Colonel BARROW: No, they are only too anxious to make them.

Captain DUNCAN STEWART of the Royal Canadian Foot Regiment stated in the course of examination that he had an attack of malarial fever at Pretoria, went into hospital there, and could not speak too highly of the medical men and the nurses.

Mr. STROMEYER LITTLE said that he went out to South Africa not in the public service but as a visitor. As a visitor he was very favourably impressed with the hospitals, but when he came to work in one he found things were a little different. In his opinion the great bulk of the private hospitals were superior to the military hospitals. He went to Bloemfontein in the beginning of May and worked in No. 9 Hospital, where he had charge of 10 marquees. The bell tents were overcrowded, but he could not say positively how many patients there were in them because the men moved out during the day. There undoubtedly was a want of bed-pans, and many patients probably lost their lives in consequence. The condensed milk was very poor. He thought there ought to have been fresh milk.

The CHAIRMAN: But Colonel Barrow, who was in charge, told us he would not have fresh milk because it was dangerous.

Mr. LITTLE: The condensed milk was certainly liable to contamination because you had got to mix it with water, and there were millions of flies about and this water was open to them. When he got down to Port Elizabeth he found responsible people who were ready to guarantee a thousand bottles of sterilised milk per day, and he wrote to No. 9 Hospital on the subject, but received no answer.

Captain TRYON gave evidence to the effect that he had been a patient in a hospital at Bloemfontein, travelled in a hospital train, and received treatment in a hospital at Wynberg, and was fairly well looked after in all these positions.

Lieutenant-Colonel COOPER of the Irish Guards, who had been engaged as a railway staff officer, spoke as to the difficulties experienced in the transport of the sick and wounded owing to the pressure of traffic for the fighting line.

Major A. P. BLENKINSOP, R.A.M.C., said he went out with No. 20 Field Hospital. His first duty was outside Bloemfontein, where the hospital was fully equipped, and where they had 106 cases of enteric fever and dysentery. The patients were well looked after and got their food. Finding some difficulty about the fresh milk he told the farmers that if they did not supply him he would commandeer their cows and send the owners to prison in Bloemfontein, and after that there was no more difficulty about fresh milk. For sick convoy purposes he suggested that there should be made up special boxes containing medical comforts, jellies, and the like, and with regard to field hospitals he thought that they should have their own transport.

Mr. A. K. BURN of the City of London Imperial Volunteers gave evidence as to his treatment for enteric fever in one of the field hospitals.

The Commission then adjourned.

The Secretary (Major TENNANT) intimated that the visit to South Africa will probably occupy two or three months, and that on its conclusion further evidence will be taken in London.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

ALDERSON, WILFRED E., M.D., M.S. Durh., has been appointed Honorary Physician to the Newcastle-on-Tyne Dispensary.

ANDERSON, THOMAS MCCALL, M.D. Glasg., has been appointed Professor of Practice of Medicine in the University of Glasgow, vice Professor Sir W. T. Gairdner, retired.

ATKINSON, C. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the Workhouse, East Ashford Union, vice C. S. Atkinson, deceased.

BEACHCROFT, F. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Second Sanitary District and the Workhouse of the Petworth Union, vice R. J. McDermott, resigned.

BISSET, A., M.B., Ch.B. Aberd., has been appointed Resident Physician to the Royal Infirmary, Aberdeen.

BLAKISTON, F. C., L.R.C.P. Lond., M.R.C.S., has been appointed Junior Assistant Medical Officer for the Infirmary of the Wandsworth and Clapham Union, vice C. Powell.

BLYTH, M. W., has been appointed Public Analyst for the County Borough of Brighton, vice E. H. Moore, resigned.

BOYD, STANLEY, M.B. Lond., F.R.C.S., has been appointed Surgeon to the Hospital for Consumption, Brompton, vice R. J. Godlee, resigned.

COOKE, L., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Aspull Sanitary District of the Wigan Union.

COWIE, WILLIAM, M.B., C.M. Aberd., has been appointed Medical Officer for the Charlton Sanitary District of the Woolwich Union, vice J. Logie, deceased.

CROLL, W. F., M.B., Ch.B. Aberd., has been appointed Resident Physician to the Royal Infirmary, Aberdeen.

CROSSFIELD, A. K., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Dartmouth Sanitary District of the Totnes Union, vice R. W. Soper, deceased.

DAY, F. W. H. L., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health by the Hitchin Urban District Council.

ELLIS, R. SIDNEY, M.B., Ch.B. Edin., has been appointed Assistant Resident Medical Officer to the St. Mary's Children's Hospital, Plaistow, E.

GOURLAY, F. T., M.B., C.M. Edin., has been appointed Medical Officer for the Shiffnal and Stockton Sanitary Districts and the Workhouse of the Shiffnal Union, vice T. H. Keogh, resigned.

GRANT, LACHLAN, M.D. Edin., has been appointed Medical Officer to the Ballachulish State Quarries, vice Dr. Farquharson, resigned.

HANCOCK, JAMES TAYLOR, L.R.C.S., L.R.C.P. Edin., has been appointed Medical Officer and Public Vaccinator to the Carlton and Drax District of the Selby Union.

HARDY, F. S., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Superintendent of the Sheffield City Hospital, vice A. Anderson, resigned.

HARTLEY, J. D., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Slaidburn Sanitary District of the Clitheroe Union, vice J. Sinclair.

HOPKINS, JAMES J., L.R.C.P., L.R.C.S. Irel., has been appointed Certifying Surgeon under the Factory Acts for the Nos. 1 and 2 Castlebar Dispensary Districts, and the Electoral Division of Bellavady, in the Union of Castlebar.

JOHNSON, H. S., M.R.C.P. Irel., L.F.P.S. Glasg., has been reappointed Medical Officer by the Ashburton Urban District Council.

POLLARD, W. R., M.R.C.P. Edin., L.R.C.S. Irel, has been appointed Medical Officer to the Cottage Homes by the Cottage Homes Committee, Blackburn.

PRITCHARD, R. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third Sanitary District of the Petworth Union, vice R. J. McDermott, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ASHANTI FIELD FORCE.—Experienced Dressers for six months in the Colony, with pay at the rate of £20 a month, and other money, &c., arrangements. Address to the Assistant Private Secretary, Colonial Office.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried. Salary £150 per annum, with an allowance of £30 yearly for cab-hire, with furnished room, fire, lights, and attendance.

BRADFORD ROYAL INFIRMARY.—Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence. Also Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

BRECON INFIRMARY, No. 6, Bulwark, Brecon, South Wales.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, fire, and gas.

BRIGHTON, HOVE, AND PRESTON DISPENSARY (WESTERN BRANCH AND COTTAGE HOSPITAL), 113, Queen's-road, Brighton.—House Surgeon. Salary £120 per annum, with board and residence.

CANCER PAVILION AND HOME, Manchester.—Surgical Officer.—Applications to Mr. E. W. Marshall, 38, Barton Arcade, Manchester.

CHESTER GENERAL INFIRMARY.—Second Resident Medical Officer. Salary £80 per annum, with residence and maintenance in the House.

CITY OF BOMBAY.—Executive Health Officer for five years, renewable conditionally. Monthly salary arranged.—Apply to the Municipal Commissioner for City of Bombay, care of Mr. John Lithiby, Local Government Board, Whitehall.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—District Surgeons to the Hospital for the Eastern Division of Bethnal Green and for South Tottenham.

COUNTY ASYLUM, Dorchester.—Second Assistant Medical Officer, unmarried. Salary £140, rising to £160 the second year.

COUNTY ASYLUM, Lancaster.—Assistant Medical Officer. Salary commencing at £125 per annum with the usual allowances.

CUMBERLAND INFIRMARY, Carlisle.—House Surgeon for one year. Salary £70 per annum, with board, lodging, and washing. Also Assistant House Surgeon for seven months from Oct. 1st. Salary at the rate of £40 per annum, with board, lodging, and washing.

STUART.—On Aug. 4th, at Gloucester-terrace, W., William Johnston Stuart, Surgeon-Major (retired) H.M. Bombay Army, aged 81.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

WHAT IS "PROPER LODGING" UNDER THE PUBLIC HEALTH ACT?"

To the Editors of THE LANCET.

SIRS,—I am advising my council to provide isolation accommodation for a large mining district with a population of about 14,000. The miners principally live in three or four-roomed cottages (in some cases five rooms) in rows or terraces. Sec. 124 P. H. Act, 1875, says: "Any person suffering from any dangerous infectious disorder and is without proper lodging or accommodation" may be removed to such hospital. What is meant by "without proper lodging and accommodation"? If the child or a person living in the house of one of these colliers is taken ill with infectious disease (diphtheria, enteric fever, &c.), is the child without proper accommodation, and could we have the power to remove it? In the case of a "lodger" in one of these houses I presume there would be no difficulty. I should be glad if you would kindly deal with the question in one of your issues. I feel that unless we have more power than the Public Health Act gives us the hospital would not be in use half the time.

I am, Sirs, yours faithfully,

August 4th, 1900. MEDICAL OFFICER OF HEALTH.

* * The question shall have our attention.—ED. L.

THE DUNMOW FLITCH.

AT the annual Dunmow Flitch celebration which took place in the presence of a crowd of holiday-makers on August 6th, the first claimants were Mr. and Mrs. Evelyn John Evatt of Newcastle-on-Tyne. Mr. Evatt is said by the newspapers to be a medical student. When the matrimonial affairs of a medical student attract the attention of the press it is so generally because of their painful nature that we are bound to congratulate Mr. Evatt upon a publicity that has its origin in his conjugal happiness.

THE FIRST GENERAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AT IPSWICH.

To the Editors of THE LANCET.

SIRS,—In your doubtless very hurried report of the first general meeting of the British Medical Association in Ipswich you insert the lines: "that THE LANCET *plébiscite* showed plainly that the feeling of the profession was against the Midwives Bill, and Mr. D. O'Sullivan." This is on p. 357, left-hand column, lines 29-30. Please note comma after Midwives Bill. There is no sense in the paragraph. And why my name was introduced I cannot understand, as any remarks I made were agreed with by the great majority of the meeting. The report also at the top of the page (same column) shows a first line which is foreign to Dr. Saundby's remarks and is evidently interpolated by carelessness. I feel that I am placed in an invidious position by the introduction of my name in the manner indicated.

I am, Sirs yours faithfully,

Southport, August 7th, 1900. DANIEL A. O'SULLIVAN.

*** We fail to see anything invidious in our report. If Mr. O'Sullivan will read the report carefully he will see that we said that he was one of the principal speakers during a certain portion of the general meeting, and it is a fact that he was so. Leaving out parenthetical clauses, the paragraph reads: "the principal speakers being Dr. Brassey Brierley, Dr. J. Haddon, Dr. A. Cox, and Mr. D. O'Sullivan."—ED. L.

"DRESSERS" FOR KUMASI.

To the Editors of THE LANCET.

SIRS,—I had occasion some two or three weeks ago to call attention to the parsimony of the Colonial Office in its attempt to obtain medical officers for an expedition to Kumasi. Whether it failed to obtain an adequate supply of qualified men for the totally inadequate remuneration offered I am not aware; but this week in your columns and in the columns of a contemporary appears an advertisement asking for "dressers." These "dressers" are offered pay at the rate of £20 a month *plus* an allowance of 5*s.* per diem, with privileges as regards passage, rations, and gratuity similar to those of the previously-advertised-for medical officer. This offer to the unqualified "dresser" appears to be as liberal as the offer to the qualified man was illiberal; the difference in the value of the services of the qualified and registered (£30 a month and no allowance) and the unqualified and unregistered (£20 a month *plus* 5*s.* a day allowance) candidate being, if the estimate of the Colonial Office is to be accepted, only some £2 10*s.* or £2 15*s.* per mensem. It was rumoured that some senior students and dressers who volunteered for service in South Africa were told off to scrub floors and clean "quarters." I do not think that these "dressers" need fear that their services will be so little appreciated, they will probably find themselves in positions of considerable responsibility. The circumstances of the case rather favour the suspicion that the previous request for medical officers at the small salary offered having elicited no very fervid response the authorities contemplate employing unqualified men under the guise of "dressers." The remuneration offered to these "dresser" candidates is ample though not extravagant, and while some "chronics" may be tempted to respond I doubt if any genuine "dresser" or "clerk" with any prospects will care to delay his curriculum and cast his chances into such a fatal lottery as a West Coast expedition.

I am, Sirs, yours faithfully,

Aug. 6th, 1900. CANTAB.

AN IMPROVED CYCLE AND MOTOR-CAR LAMP.

OUR attention has been drawn to an improved cycle and motor-car lamp which, if generally in use, would do much to prevent accidents and reduce the strain upon the nerves which accrues from riding at night. Medical men who use the cycle for night calls would find increased comfort from the use of the lamp, for there is practically no danger of being run down from behind, while the rider is able to see his pedals for mounting. The improvement is extremely simple and consists in affixing at each side of the lamp a glass prism placed in an oblique direction from above downward and forward. One of the faces of the prism is almost at right angles to the side of the lamp and throws a beam of light backward and downward. Mr. John Cassels of 76, Hall-street, Stockport, is the inventor and the lamps are sold in two qualities, at the prices of 6*s.* and 15*s.*, the high-priced lamp being an excellent production of the lamp-maker's art.

A BUST OF SIR RICHARD OWEN.

To the Editors of THE LANCET.

SIRS,—Can you kindly advise me where a bust of Sir Richard Owen would be likely to be purchased? The original was executed by the late Mr. Hodges Baily, R.A., who executed Nelson's monument on the column in Trafalgar-square, I believe, and the bust in plaster is from the original, and is the work of Mr. Baily also. It is in the possession of his granddaughters, ladies in very poor circumstances. They would accept £10 10*s.* for it—at which price, I believe, a similar bust has been previously sold. Being in Ipswich for the annual meeting of the British Medical Association has enabled me to inspect the bust, which is life-size and in good condition. It is on their behalf that I venture to ask your kind assistance in disposing of the bust, which might be much valued by a public institution.—I am, Sirs, yours faithfully,

EDGAR DUKE, M.D. Durh.

11, Wilbury-road, Hove, August 3rd, 1900.

AUTO-INTOXICATION IN PREGNANCY.

To the Editors of THE LANCET.
